Every thing settled in the capitulation ought to be sacred and inviolable, and should be understood in its genuine and most natural sense: yet as this is not always practised, the governor should take the utmost precaution to have no word inserted that shall be in the least equivocal, or liable to different interpretations. There are a great many examples which prove the necessity of this precaution.

When the garrison of a town capitulate in order to retire to the citadel, there are some particular conditions to be observed; such as follow.

That the citadel shall not be attacked on the side next the town; that the sick and wounded, who cannot be removed, shall stay in their present lodgings; and when they are recovered, they shall be provided with carriages and transports to retire in safety to the place agreed on in the capitulation. None should be suffered to enter the citadel, but those who may be of use in defending it; the rest, who are called *useless mouths*, by no means ought to be admitted. Mention should be made in the capitulation, that those people shall be conducted to some neighbouring place in the dominions of their sovereign, which should be named. A certain time ought also to be allowed for the whole garrison to enter the citadel; and it should be expressly mentioned, that during this time the besiegers shall

construct no works that are necessary for the reduction of the citadel.

A maritime town requires also some particular attention, in regard to the ships that may be in the harbour. It should be stipulated, that they shall quit the harbour the same day as the garrison march out of the town, or when the weather permits to sail to the port agreed upon. They should preserve their artillery, rigging, ammunition and provisions, &c. If they should be obliged by fleets of weather to put into any harbour of the besiegers by the way, it ought to be mentioned in the capitulation, that they shall be received there, and supplied with necessaries for continuing their voyage; they ought also to be provided with passports, and, in a word, to have every kind of security, that they shall not be insulted by the enemy's ships, but suffered without the least obstacle to steer to the port agreed upon.

WAR

Man of WAR Bird. See PELICANUS.

WAR-Cry was formerly customary in the armies of most nations, when just upon the point of engaging. Sometimes they were only tumultuous shouts, or horrid yells, uttered with an intent to strike terror into their adversaries; such as is now used by the Indians in America, called the *war-whoop*.

WARBLES, in farrery See there § xxxii.

WARBURTON (William), who has been justly styled *vir magnus, acer, memorabilis*, was descended from an ancient and considerable family in Cheshire. His grandfather distinguished himself in the civil wars of the last century; and being of the royal party, probably injured his fortune by his attachment to his king and the constitution of his country. He married a lady of the county of Nottingham, by whom he had three sons; the second of whom, George, being bred to the law, practised as an attorney at Newark in that county.

William, the subject of this memoir, and the second son of Mr George Warburton, was born at Newark, December 24. 1698. He was first put to school there under a Mr Twells, but had the chief part of his education at Okeham in Rutlandshire, where he continued till the beginning of the year 1714, when, his cousin being made head master of the school at Newark, he returned to his native place, and was for a very short time under the care of that learned and respectable relation. In the month of April of the same year, he was put out clerk to Mr Kirke, an eminent attorney of Great Markham in Nottinghamshire; and continued with that gentleman till the spring of the year 1719. He then returned to his family at Newark; but whether he practised there or elsewhere as an attorney, is not known to his accomplished biographer, the bishop of Worcester.

He had always expressed a strong inclination to take orders; and the love of letters, which tended to retard, rather than forward, his progress in the profession chosen for him by his friends, growing every day stronger in him, it was deemed expedient to give way to that inclination. In the studies necessary to fit him for the church, he was directed by his cousin the schoolmaster of Newark; to whom, long afterwards, when he stood himself in the very front of literature, he gratefully acknowledged his obligations. At length, on the 22d of December 1723, he was ordained deacon by archbishop Davis of York, and priest on the first of March 1727, by bishop Gibson of London.

Though he never liked the profession of an attorney, he

WAR

had certainly acquired a very considerable knowledge of the laws of England; for in a dispute which arose in 1726, about the judicial power of the court of chancery, he combated with success the opinions of no less a man than the lord chancellor Hardwicke, then attorney-general.

In 1728 he was presented by Sir Robert Sutton to the rectory of Brand-Broughton, in the diocese of Lincoln, where he spent the greater part of his life, and composed all the great works which will carry his fame down to posterity. In the same year he was put upon the king's list of Masters of Arts, erected on his majesty's visit to the university of Cambridge. He had already published some juvenile performances, which displayed genius and reading, and attracted considerable notice; but it was not till the year 1736 that he may be said to have emerged from the obscurity of a private life into the notice of the world.—The first publication which rendered him afterwards famous now appeared, under the title of "The Alliance between Church and State; or, the Necessity and Equity of an Established Religion and a Test Law; demonstrated from the Essence and End of Civil Society, upon the fundamental Principles of the Law of Nature and Nations." In this treatise, says Bishop Horsley †, the author "hath shown the general good policy of an establishment, and the necessity of a Test for its security, upon principles which republicans themselves cannot easily deny. His work is one of the finest specimens that are to be found perhaps in any language, of scientific reasoning applied to a political subject."

Warburton.

Review of the Cause of the Protestant Dissenters, Lond. 1757. PREF.

At the close of the Alliance was announced the scheme of the Divine Legation of Moses, in which he had then made a considerable progress. The first volume of this work was published in January 1737-8, under the title of "The Divine Legation of Moses demonstrated on the Principles of a religious Deist, from the Omission of the Doctrine of a future State of Rewards and Punishments in the Jewish Dispensation, in six books, by William Warburton, M. A. author of the Alliance between Church and State;" and met with a reception which neither the subject, nor the manner in which it was treated, seemed to authorize. It was, as the author afterwards observed, fallen upon in so outrageous and brutal a manner as had been scarce pardonable, had it been "The Divine Legation of Mahomet."—It produced several answers, and so much abuse from the authors of "The Weekly Miscellany," that in less than two months he was constrained to defend himself, in "A Vindication of the Author of the Divine Legation

Warbur-
ton.

gation of Moses, from the Aspersions of the Country Clergyman's Letter in the Weekly Miscellany of February 24. 1737-8, 8vo."

Mr Warburton's extraordinary merit had now attracted the notice of the heir apparent to the crown, in whose immediate service we find him in June 1738, when he published "Faith working by Charity to Christian Edification, a Sermon, preached at the last episcopal Vistation for Confirmation in the Diocese of Lincoln; with a Preface, showing the Reasons of its Publication; and a Postscript, occasioned by some Letters lately published in the Weekly Miscellany, by William Warburton, M. A. Chaplain to his Royal Highness the Prince of Wales."

In March 1737, the world was in danger of being deprived of this extraordinary genius by an intermitting fever, which with some difficulty was relieved by a plentiful use of the bark.

The "Essay on Man" had been now published some years; and it is universally supposed, that the author had, in the composition of it, adopted the philosophy of the Lord Bolingbroke, whom, on this occasion, he had followed as his guide, without understanding the tendency of his principles. In 1738, M. de Croufaz wrote some remarks on it, accusing the author of Spinozism and Naturalism; which falling into Mr Warburton's hands, he published a defence of the first epistle, and soon after of the remaining three, in seven letters; of which six were printed in 1739, and the seventh in June 1740, under the title of "A Vindication of Mr Pope's Essay on Man, by the author of the Divine Legation." The opinion which Mr Pope conceived of these defences, as well as of their author, will be best seen in his letters. In consequence, a firm friendship was established between them, which continued with undiminished fervour until the death of Mr Pope; who, during the remainder of his life, paid a defence and respect to his friend's judgment and abilities, which will be considered by many as almost bordering on servility.

Towards the end of the year 1739, Mr Warburton published a new and improved edition of the first volume of the Divine Legation; and in May 1741, appeared the second part, which completed the argument, though not the entire plan of that work. "A work, says Bishop Hurd †, in all views of the most transcendent merit, whether we consider the invention or the execution. A plain simple argument, yet perfectly new, proving the divinity of the Mosaic law, and laying a sure foundation for the support of Christianity, is there drawn out to a great length by a chain of reasoning so elegantly connected, that the reader is carried along it with ease and pleasure; while the matter presented to him is so striking for its own importance, so embellished by a lively fancy, and illustrated from all quarters by exquisite learning and the most ingenious disquisition, that in the whole compass of modern or ancient theology, there is nothing equal or similar to this extraordinary performance."

This is the panegyric of a man reflecting with tenderness on the memory of his friend and benefactor; but it approaches much nearer to the truth than the censures of those cabalistic critics, who, fastening upon some weak part of the Divine Legation, or perhaps never having looked into it, have ridiculously contended that the author was far from being eminent as a scholar (A), and that his work is inimical to the cause of Christianity! Putting partiality aside,

there is in the Divine Legation of Moses abundant evidence of the malignant folly of this charge, as no man can read and understand that work without being convinced that its author was a Christian, not only sincere but zealous; that he was, what Johnson calls him *, "a man of vigorous faculties, of a mind fervid and vehement, supplied by unlimited and incessant inquiry, with a wonderful extent and variety of knowledge, which had neither depressed his imagination nor clouded his perspicuity; and that to every work, and this work in particular, he brought a memory full fraught, with a fancy fertile of original combinations, exerting at once the powers of the scholar, the reasoner, and the wit." But we think it must be acknowledged, that his learning was too multifarious to be always exact, and his inquiries too eagerly pushed to be always cautious. We have no hesitation, however, to say, that to the divine this great work, with all its imperfections, is, in our opinion, one of the most valuable that is to be found in any language.

In the summer 1741, Mr Pope and Mr Warburton, in a country ramble, took Oxford in their way. The university was naturally pleased at the arrival of two such strangers, and seemed desirous of enrolling their names among their graduates. The degree of D. D. was intended for the divine, and that of L. L. D. for the poet; but intrigue and envy defeated this scheme; and the university lost the honour of decorating at the same time the two greatest geniuses of the age, by the fault of one or two of its members. Pope retired with some indignation to Twickenham, where he consoled himself and his friend with this sarcastic reflection—"We shall take our degree together in fame, whatever we do at the university."

The friendship of this eminent poet was of service to Mr Warburton in more respects than that of increasing his fame. He introduced and warmly recommended him to most of his friends, and among others to Mr Murray, afterwards earl of Mansfield, and Ralph Allen, Esq; of Prior-park. In consequence of this introduction, we find Mr Warburton at Bath 1742; where he printed a sermon which had been preached at the Abbey church on the 24th of October, for the benefit of Mr Allen's favourite charity, the General Hospital or Infirmary. In this year also he printed a Dissertation on the origin of books of chivalry, at the end of Jarvis's Preface to a translation of Don Quixote, which Mr Pope tells him, he had not got over two paragraphs of, before he cried out, *Aut Erasmus, aut Diabolus.*

In 1742, Mr Warburton published "A Critical and Philosophical Commentary on Mr Pope's Essay on Man. In which is contained a Vindication of the said Essay from the Misrepresentation of M. de Resnal, the French Translator, and of M. de Croufaz, Professor of Philosophy and Mathematics in the Academy of Lausanne, the Commentator." It was at this period, when Mr Warburton had the entire confidence of Mr Pope, that he advised him to complete the Dunciad, by changing the hero, and adding to it a fourth book. This was accordingly executed in 1742, and published early in 1743, with notes by our author; who, in consequence of it, received his share of the abuse which Mr Cibber liberally bestowed on both Mr Pope and his annotator. In the latter end of the same year he published complete editions of "The Essay on Man," and "The Essay on Criticism;" and from the specimen which he there exhibited of his abilities, it may be presumed Mr
Pope

† Life of
Warburton
prefixed to
his Works.

(A) We have heard this affirmed by narrow-minded clergymen, who were destitute themselves of every spark of science, and had no other claim to literature than what arose from a slight acquaintance with Hebrew critics of a very peculiar cast; to whom, it must be owned, that no great respect was indeed ever paid by the author of the Divine Legation of Moses.

Pope determined to commit the publication of those works which he should leave to Mr Warburton's care. At Mr Pope's desire, he, about this time, revised and corrected the "Essay on Homer," as it now stands in the last edition of that translation.

The publication of "The Dunciad" was the last service which our author rendered Mr Pope in his lifetime. After a lingering and tedious illness, the event of which had been long foreseen, this great poet died on the 30th of May 1744; and by his will, dated the 12th of the preceding December, bequeathed to Mr Warburton one half of his library, and the property of all such of his works already printed as he had not otherwise disposed of or alienated, and all the profits which should arise from any edition to be printed after his death; but at the same time directed that they should be published without any future alterations.

"In 1744, Mr Warburton turned his attention to the several attacks which had been made on the "Divine Legation," and defended himself in a manner which, if it did not prove him to be possessed of much humility or diffidence, at least demonstrated, that he knew how to wield the weapons of controversy with the hand of a master. His first defence now appeared, under the title of "Remarks on several occasional Reflections, in Answer to the Reverend Dr Middleton, Dr Pococke, the Master of the Charter-House, Dr Richard Grey, and others; serving to explain and justify divers Passages in the Divine Legation, objected to by those learned Writers. To which is added, A General Review of the Argument of the Divine Legation, as far as it is yet advanced; wherein is considered the Relation the several Parts bear to each other and the whole. Together with an Appendix, in Answer to a late Pamphlet intitled, An Examination of Mr W——'s second Proposition." This was followed next year by "Remarks on several occasional Reflections, in Answer to the Reverend Doctors Stebbing and Sykes; serving to explain and justify the Two Dissertations in the Divine Legation, concerning the Command to Abraham to offer up his Son, and the Nature of the Jewish Theocracy, objected to by these learned Writers. Part II. and last." Both these answers are couched in those high terms of confident superiority, which marked almost every performance that fell from his pen during the remainder of his life.

On the 5th of September 1745, the friendship between him and Mr Allen was more closely cemented by his marriage with Miss Tucker, who survived him, and is now, if alive, Mrs Stafford Smith of Prior-park. At that important crisis our author preached and published three seasonable sermons: 1. "A faithful Portrait of Popery, by which it is seen to be the Reverse of Christianity, as it is the Destruction of Morality, Piety, and Civil Liberty. Preached at St James's, Westminster, October 1745." 2. "A Sermon occasioned by the present unnatural Rebellion, &c. Preached in Mr Allen's Chapel at Prior park, near Bath, November 1745." 3. "The Nature of National Offences truly stated.—Preached on the General Fast-day, December 18. 1745-6." On account of the last of these sermons, he was again involved in a controversy with his former antagonist Dr Stebbing, which occasioned "An Apologetical Dedication to the Reverend Dr Henry Stebbing, in Answer to his Cenlure and Misrepresentations of the Sermon preached on the General Fast, &c."

Notwithstanding his great connections, his acknowledged abilities, and his established reputation, a reputation founded on the durable basis of learning, and upheld by the decent and attentive performance of every duty incident to his station; yet we do not find that he received any addi-

tion to the preferment given him in 1728 by Sir Robert Sutton (except the chaplainship to the prince of Wales), until April 1746, when he was unanimously called by the Society of Lincoln's Inn to be their preacher. In November he published "A Sermon preached on the Thanksgiving appointed to be observed the 9th of October, for the Suppression of the late unnatural Rebellion." In 1747 appeared his edition of Shakspeare, and his Preface to Clarissa; and in the same year he published, 1. "A Letter from an Author to a Member of Parliament concerning Literary Property." 2. "Preface to Mrs Cockburn's Remarks upon the Principles and Reasonings of Dr Rutherford's Essay on the Nature and Obligations of Virtue," &c. 3. "Preface to a Critical Inquiry into the Opinions and Practice of the ancient Hebraeans, concerning the Nature of a Future State, and their Method of teaching by double Doctrine," (by Mr T. Wane) 1747, second edition. In 1748, a third edition of "The Alliance between Church and State, corrected and enlarged."

"In 1749, a very extraordinary attack was made on the moral character of Mr Pope, from a quarter where it could be the least expected. An insignificant pamphlet, under the name of *A Patent King*, was that year published by Lord Bolingbroke, or by his direction, with a preface to it, reflecting highly on Mr Pope's honour. The provocation was simply this: The manuscript of that trivial declaration had been intrusted to the care of Mr Pope, with the charge (as it was pretended) that only a *certain* number of copies should be printed. Mr Pope, in his excellent administration of his *guide*, *philosopher*, and friend, took that opportunity, for fear to invaluable a treasure of patriot eloquence should be lost to the public, to exceed his commission, and to run off more copies, which were found, after his death, in the printer's warehouse. This charge, however frivolous, was aggravated beyond measure; and, notwithstanding the proofs which Lord Bolingbroke had received of Pope's devotion to him, envenomed with the most malignity. Mr Warburton thought it became him to vindicate his deceased friend; and he did it so effectually, as not only to silence his accuser, but to cover him with confusion †."

About this time the publication of Dr Middleton's Inquiry concerning the miraculous Powers of the Christian Church, gave rise to a controversy, which was managed with great warmth and asperity on both sides, and not much to the credit of either party. On this occasion Mr Warburton published an excellent performance, written with a degree of candour and temper, which, it is to be lamented, he did not always exercise. The title of it was "Julian; or a Discourse concerning the Earthquake and fiery Eruption which defeated that Emperor's attempt to rebuild the Temple at Jerusalem, 1750." A second edition of this discourse, "with Additions," appeared in 1751, in which year he gave the public his edition of Mr Pope's Works, with Notes, in nine volumes 8vo; and in the same year printed "An Answer to a Letter to Dr Middleton, inserted in a Pamphlet intitled, The Argument of the Divine Legation fairly stated," &c.; and "An Account of the Prophecies of Arise Evans, the Welsh Prophet in the last Century," annexed to the first volume of Dr Jortin's Remarks on Ecclesiastical History, which afterwards subjected him to much trouble.

In 1752, Mr Warburton published the first volume of a course of sermons, preached at Lincoln's Inn, intitled, "The Principles of Natural and Revealed Religion, occasionally opened and explained;" and this was two years afterwards followed by a second. After the public had been some time promised, it may, from the alarm which was taken, be almost said threatened with, the appearance of Lord Bolingbroke's Works, they were about this time printed.

† *Warburton's*

printed. The known abilities and infidelity of this nobleman had created apprehensions in the minds of many people, of the pernicious effects of his doctrines; and nothing but the appearance of his whole force could have convinced his friends, how little there was to be dreaded from arguments against religion so weakly supported. Many answers were soon published, but none with more acuteness, solidity, and spiritfulness, than "A View of Lord Bolingbroke's Philosophy, in two Letters to a Friend, 1754;" the third and fourth letters were published in 1755, with another edition of the two former; and in the same year a smaller edition of the whole; which, though it came into the world without a name, was universally ascribed to Mr Warburton, and afterwards publicly owned by him. To some copies of this is prefixed an excellent complimentary epistle from the President Montaigne, dated May 26. 1754.

At this advanced period of his life, that preferment which his abilities might have claimed, and which had hitherto been withheld, seemed to be approaching towards him. In September 1754, he was appointed one of his Majesty's chaplains in ordinary, and in the next year was presented to a prebend in the cathedral of Durham, on the death of Dr Mangey. About this time the degree of Doctor of Divinity was conferred on him by Dr Herring, then archbishop of Canterbury. A new impression of *The Divine Legation* being now called for, he printed a fourth edition of the first part of it, corrected and enlarged, divided into two volumes, with a dedication to the earl of Hardwicke. The same year appeared "A Sermon preached before his Grace Charles Duke of Marlborough, President, and the Governors of the Hospital for the Small-pox and for Inoculation, at the Parish-church of St Andrew, Holborn, April the 24th, 1755." And in 1756, "Natural and Civil Events the Instruments of God's Moral Government; a Sermon, preached on the last public Fast-day, at Lincoln's Inn Chapel."

In 1757, Dr Warburton meeting with Mr Hume's tract, entitled, *The Natural History of Religion*, filled the margin of the book, as well as some interleaved slips of paper, with many severe and shrewd remarks on the infidelity and naturalism of the author. These he put into the hands of his friend Dr Hurd, who, making a few alterations of the style, added a short introduction and conclusion, and published them in a pamphlet, entitled, "Remarks on Mr David Hume's Natural History of Religion, by a Gentleman of Cambridge, in a Letter to the Reverend Dr Warburton." This lively attack upon Mr Hume gave him so much offence, that he thought proper to vent his spleen on the supposed author, in the posthumous discourse which he called his *Life*; and thus to do greater honour to Dr Hurd than to any other of his numerous antagonists.

Towards the end of the year 1757, Dr Warburton was promoted to the deanery of Bristol; and in the beginning of the year 1760, he was, through Mr Allen's interest with Mr Pitt, afterwards earl of Chatham, advanced to the bishopric of Gloucester. That great minister is known to have declared, "that nothing of a private nature, since he had been in office, had given him so much pleasure as bringing our author on the bench." There was, however, another minister, who dreaded his promotion, and thought that he saw a second Atterbury in the new bishop of Gloucester; but Warburton, says bishop Hurd, had neither talents nor inclination for parliamentary intrigue or parliamentary eloquence: he had other instruments of fame in his hands, and was infinitely above the vanity of being caught

"With the fine notion of a busy man ‡."

He was consecrated on the 20th of January 1760, and

on the 30th of the same month preached before the house of lords. In the next year he printed "A Rational Account of the Nature and End of the Sacrament of the Lord's Supper." In 1762, he published "The Doctrine of Grace; or the Office and Operations of the Holy Spirit vindicated from the Insults of Infidelity and the Abuses of Fanaticism," 2 vols 12mo; and in the succeeding year drew upon himself much illiberal abuse from some writers of the popular party, on occasion of his complaint in the house of lords, on the 15th of November 1763, against Mr Wilkes, for putting his name to certain notes on the inamous "Essay on Woman."

In 1765 he published a new edition of the second part of the *Divine Legation*, in three volumes; and as it had now received his last hand, he presented it to his great friend Lord Mansfield, in a dedication which deserves to be read by every person who esteems the well being of society as a concern of any importance. It was the appendix to this edition which produced the well-known controversy between him and Dr Lowth, which we have noticed elsewhere (see *Lowth*), as doing no great honour, by the mode in which it was conducted, to either party. In the next year he gave a new and much improved edition of the *Alliance between the Church and State*. This was followed, in 1767, by a third volume of sermons, to which is added, his first Triennial Charge to the Clergy of the Diocese of Gloucester; which may be safely pronounced one of the most valuable discourses of the kind that is to be found in our own or any other language. With this publication he closed his literary course; except that he made an effort towards publishing, and actually printed, the ninth and last book of the *Divine Legation*. This book, with one or two occasional sermons, and some valuable directions for the study of *theology*, have been given to the world in the splendid edition of his works in seven volumes 4to, by his friend and biographer the present bishop of Worcester. That prelate confesses, that the ninth book of the *Divine Legation* displays little of that vigour of mind and fertility of invention which appear so conspicuous in the former volumes; but he adds, perhaps truly, that under all the disadvantages with which it appears, it is the noblest effort which has hitherto been made to give a *rationale* of Christianity.

While the bishop of Gloucester was thus exerting his last strength in the cause of religion, he projected a method by which he hoped to render it effectual service after his death. He transferred L. 500 to Lord Mansfield, Sir Eardley Wilmot, and Mr Charles Yorke, upon trust, to found a lecture, in the form of a course of sermons, to prove the truth of revealed religion in general, and of the Christian in particular, from the completion of the prophecies in the Old and New Testament, which relate to the Christian church, especially to the apostacy of Papal Rome. To this foundation we owe the admirable Introductory Lectures of Hurd, and the well-adapted Continuation of Halifax and Bagot.

It is a melancholy reflection, that a life spent in the constant pursuit of knowledge, frequently terminates in the loss of those powers, the cultivation and improvement of which are attended to with too strict and unabated a degree of ardour. This was in some degree the misfortune of Dr Warburton. Like Swift, and the great duke of Marlborough, he gradually sunk into a situation in which it was a fatigue to him to enter into general conversation. There were, however, a few old and valuable friends, in whose company, even to the last, his mental faculties were exerted in their wonted force; and at such times he would appear cheerful for several hours, and on the departure of his friends retreat as it were within himself. This melancholy habit

‡ Dryden.

habit was aggravated by the loss of his only son, a very promising young gentleman, who died of a consumption but a short time before the Bishop, who himself resigned to fate in the 81st year of his age. A neat marble monument has been erected to him in the cathedral of Gloucester, with this inscription—

To the Memory of
WILLIAM WARBURTON, D. D.
For more than 19 Years Bishop of this See;
A Prelate
Of the most sublime Genius, and exquisite Learning.
Both which Talents
He employed, through a long Life,
In the Support
Of what he firmly believed,
THE CHRISTIAN RELIGION;
And
Of what he esteemed the best Establishment of it,
THE CHURCH OF ENGLAND.
He was born at Newark upon Trent,
Dec. 24. 1693.
Was consecrated BISHOP of Gloucester,
Jan. 20. 1760.
Died at his Palace, in this City,
June 7. 1779.
And was buried near this Place.

WARD (Dr Seth), an English prelate chiefly famous for his knowledge in mathematics and astronomy, was born at Buntingford in Hertfordshire, about the year 1617. He was admitted of Sidney college Cambridge, where he applied with great vigour to his studies, particularly to the mathematics, and was chosen fellow of his college. He was involved not a little in the consequences of the civil war, but soon after the Restoration obtained the bishopric of Exeter; in 1667, he was translated to Salisbury; and in 1671 was made chancellor of the order of the garter; he was the first Protestant bishop that enjoyed that honour, and he procured it to be annexed to the see of Salisbury. Bishop Ward was one of those unhappy persons who have the misfortune to survive their tenets, which happened in consequence of a fever ill cured; he lived to the Revolution, without knowing any thing of the matter, and died in 1690. He was the author of several Latin works in mathematics and astronomy, which were thought excellent in their day; but their use has been superseded by later discoveries and the Newtonian philosophy.

WARD (Dr John), was the son of a dissenting minister, and born at London in 1679. He for some years kept a school in Tenter-alley, Moorfields; but rendered himself so eminent in the study of antiquity, that in 1720 he was chosen professor of rhetoric in Gresham college: in 1723, during the presidency of Sir Isaac Newton, he was elected a fellow of the Royal Society; and in 1752 one of the vice-presidents, in which office he was continued to his death. He was elected one of the trustees of the British Museum in 1753, and died at Gresham college in 1758. The work for which he is best known, is his Lives of the Professors of Gresham College: which is a considerable addition to the history of learning in our country. His Lectures on Oratory were published after his death, in two volumes 8vo.

WARD, is variously used in our old books: a ward in London is a district or division of the city, committed to the special charge of one of the aldermen; and in London there are 26 wards, according to the number of the mayor and aldermen, of which every one has his ward for his proper guard and jurisdiction. A forest is divided into

wards; and a prison is called a *ward*. Lastly, the heir of the king's tenant, that held *in capite*, was termed a *ward* during his nonage; but this wardship is taken away by the statute 12 Car. II. c. 24.

WARD-Holding, in Scots law. See LAW, N. clxv. 1. and clxvi. 3.

WARD Hook, or *Wadd-hook*, in gunnery, a rod or staff, with an iron end turned serpentwise, or like a screw, to draw the wadding out of a gun when it is to be unloaded.

WARDEN, or GUARDIAN, one who has the charge or keeping of any person, or thing, by office. Such is the warden of the Fleet, the keeper of the Fleet prison, who has the charge of the prisoners there, especially such as are committed from the court of chancery for contempt.

WARDHUIYS, a port of Norwegian Lapland, 120 miles south-east of the North Cape. E. Long. 31. 12. N. Lat. 77. 23

WARDMOTE, in London, is a court so called, which is kept in every ward of the city; answering to the *urista comitia* of Rome.

WARDROBE, a closet or little room adjoining to a bed-chamber, serving to dispose and keep a person's apparel in; or for a servant to lodge in, to be at hand to wait, &c.

Ward-robe, in a prince's court, is an apartment wherein his robes, wearing apparel, and other necessaries, are preserved under the care and direction of proper officers.

In Britain, the *Master or Keeper of the Great Wardrobe* was an officer of great antiquity and dignity. High privileges and immunities were conferred on him by king Henry VI. which were confirmed by his successors; and king James I. not only enlarged them, but ordained that this office should be a corporation or body politic for ever.

It was the duty of this office to provide robes for the coronations, marriages, and funerals of the royal family; to furnish the court with hangings, cloths of state, carpets, beds, and other necessaries; to furnish houses for ambassadors at their first arrival; cloths of state, and other furniture, for the lord lieutenant of Ireland, and all his majesty's ambassadors abroad; to provide all robes for foreign knights of the garter, robes for the knights of the garter at home; robes and all other furniture for the officers of the garter; coats for kings, heralds, and pursuivants at arms; robes for the lords of the treasury, and chancellor of the exchequer, &c. livery for the lord chamberlain, rooms or his majesty's privy chamber, officers of his majesty's robes; for the two chief justices, for all the barons of the exchequer, and several officers of these courts; all liveries for his majesty's servants, as yeoman of the guard, and wardens of the Tower, trumpeters, kettle-drummers, drummers, and btes; the messengers, and all belonging to the stables, as coachmen, footmen, littermen, postillions, and grooms, &c. all the king's coaches, chariots, harnesses, saddles, bits, bridles, &c. the king's water-men, game-keepers, &c. also furniture for the royal yachts, and all rich embroidered tilts, and other turniture for the barges.

Besides the master or keeper of the wardrobe, who had a salary of L. 2000, there was his deputy, who had L. 150, and comptroller and a patent clerk, each of whom has a salary of L. 300. Besides many other inferior officers and servants, who were all sworn servants to the king.

There was likewise a removing wardrobe, who had its own set of officers, and standing wardrobe-keepers at St James's, Windsor Castle, Hampton Court, Kensington, and Somerset House; but the whole of the wardrobe establishment was abolished by act of Parliament in 1783, and the duty of it in future to be done by the lord chamberlain.

WARDSHIP, in chivalry, one of the incidents of tenure

Ward
War ship.

Beston's
Political In-
dex, vol. ii.

Wardship. nure by knight-service. See *FEODAL System*, *KNIGHT Service*, and *TENURE*.

Upon the death of a tenant, if the heir was under the age of 21, being a male, or 14, being a female, the lord was intitled to the wardship of the heir, and was called the *guardian in chivalry*. This wardship consisted in having the custody of the body and lands of such heir, without any account of the profits, till the age of 21 in males, and 16 in females. For the law supposed the heir-male unable to perform knight-service till 21; but 28 for the female, she was supposed capable at 14 to marry, and then her husband might perform the service. The lord therefore had no wardship, if at the death of the ancestor the heir-male was of the full age of 21, or the heir-female of 14; yet if she was then under 14, and the lord once had her in ward, he might keep her so till 16, by virtue of the statute of Westminster, 1. 3 Edw. I. c. 22. the two additional years being given by the legislature for no other reason but merely to benefit the lord.

This wardship, so far as it related to land, though it was not nor could be part of the law of lands, so long as they were arbitrary, temporary, or for life only; yet when they became hereditary, and did consequently often descend upon infants, who by reason of their age could neither perform nor stipulate for the services of the feud, does not seem upon feodal principles to have been unreasonable. For the wardship of the land, or custody of the feud, was retained by the lord, that he might out of the profits thereof provide a fit person to supply the infant's services till he should be of age to perform them himself. And if we consider a feud in its original import, as a stipend, fee, or reward for actual service, it could not be thought hard that the lord should withhold the stipend so long as the service was suspended. Though undoubtedly to our English ancestors, where such stipendary donation was a mere supposition or figment, it carried abundance of hardship; and accordingly it was relieved by the charter of Henry I. which took this custody from the lord, and ordained that the custody, both of the land and the children, should belong to the widow or next of kin. But this noble immunity did not continue many years.

The wardship of the body was a consequence of the wardship of the land; for he who enjoyed the infant's estate was the properest person to educate and maintain him in his infancy: and also in a political view, the lord was most concerned to give his tenant a suitable education, in order to qualify him the better to perform those services which in his maturity he was bound to render.

When the male heir arrived to the age of 21, or the heir-female to that of 16, they might sue out their livery or *ousterlemain*; that is, the delivery of their lands out of their guardian's hands. For this they were obliged to pay a fine, namely, half-a-year's profits of the land; though this seems expressly contrary to *magna charta*. However, in consideration of their lands having been so long in ward, they were excused all reliefs, and the king's tenants also all primer feifins. In order to ascertain the profits that arose to the crown by these fruits of tenure, and to grant the heir his livery, the itinerant justices, or justices in eyre, had it formerly in charge to make inquisition concerning them by a jury of the county, commonly called an *inquisitio post mortem*; which was instituted to inquire (at the death of any man of fortune) the value of his estate, the tenure by which it was holden, and who, and of what age, his heir was; thereby to ascertain the relief and value of the primer feifin, or the wardship and livery accruing to the king thereupon. A manner of proceeding that came in process of time to be greatly abused, and at length an intolerable grievance; it being one of the

principal accusations against Empson and Dudley, the wicked engines of Henry VII. that by colour of false inquisitions they compelled many persons to sue out livery from the crown, who by no means were tenants thereunto. And afterwards a court of wards and liveries was erected, for conducting the same inquiries in a more solemn and legal manner.

When the heir thus came of full age, provided he held a knight's fee, he was to receive the order of knighthood, and was compellable to take it upon him, or else pay a fine to the king. For in those heroic times no person was qualified for deeds of arms and chivalry who had not received this order, which was conferred with much preparation and solemnity. We may plainly discover the footsteps of a similar custom in what Tacitus relates of the Germans, who, in order to qualify their young men to bear arms, presented them in a full assembly with a shield and lance; which ceremony is supposed to have been the original of the feodal knighthood. This prerogative, of compelling the vassals to be knighted, or to pay a fine, was expressly recognised in parliament by the statute *de militibus*, 1 Edw. II.; was exerted as an expedient for raising money by many of our best princes, particularly by Edw. VI. and Q. Elizabeth; but this was the occasion of heavy murmurs when exerted by Charles I.: among whose many misfortunes it was, that neither himself nor his people seemed able to distinguish between the arbitrary stretch and the legal exertion of prerogative. However, among the other concessions made by that unhappy prince before the fatal recourse to arms, he agreed to divest himself of this undoubted flower of the crown; and it was accordingly abolished by statute 16 Car. I. c. 20.

WARE, a town of Hertfordshire, with a market on Tuesdays, and a fair on the last Tuesday in April, and Tuesday before St Matthew's day (Sep. 21.) for horses and other cattle. It is a large, well frequented, and well inhabited thoroughfare town, seated on the river Lea, 21 miles north of London. It carries on a great trade in malt and corn, which they are continually sending in large quantities to London. E. Long 0. 3. N. Lat. 51. 50.

WARN, in law, is to summon a person to appear in a court of justice.

WARNING of *TENANTS*, in Scots law. See *LAW*, N^o clxvii. 16.

WARP, in the manufactures, a name for the threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and across which the workman, by means of his shuttle, passes the threads of the woof, to form a cloth, ribband, fustian, or the like.

WARP, a small rope employed occasionally to remove a ship from one place to another, in a port, road, or river. And hence,

To *WARP*, is to change the situation of a ship, by pulling her from one part of a harbour, &c. to some other, by means of warps, which are attached to buoys; to anchors sunk in the bottom; or to certain stations upon the shore, as posts, rings, trees, &c. The ship is accordingly drawn forwards to those stations, either by pulling on the warps by hand, or by the application of some purchase, as a tackle, windlass, or capstern, upon her deck.

When this operation is performed by the ship's lesser anchors, these machines, together with their warps, are carried out in the boats alternately towards the place where the ship is endeavouring to arrive: so that when she is drawn up close to one anchor, the other is carried out to a competent distance before her, and being sunk, serves to fix the other warp, by which she is farther advanced.

Warping is generally used when the sails are unbent, or

when they cannot be successfully employed, which may either arise from the unfavourable state of the wind, the opposition of the tide, or the narrow limits of the channel.

WARRANTICE, in Scots law. See LAW, No clxiv. II.

WARRANT, is a power and charge to a constable or other officer to apprehend a person accused of any crime. It may be issued, in extraordinary cases by the privy council, or secretaries of state; but most commonly it is issued by justices of the peace. This they may do in any cases where they have a jurisdiction over the offence, in order to compel the person accused to appear before them; for it would be absurd to give them power to examine an offender, unless they had also power to compel him to attend and submit to such examination. And this extends to all treasons, felonies, and breaches of the peace; and also to all such offences as they have power to punish by statute. Before the granting of the warrant, it is fitting to examine upon oath the party requiring it, as well to ascertain that there is a felony or other crime actually committed, without which no warrant should be granted; as also to prove the cause and probability of suspecting the party against whom the warrant is prayed.

This warrant ought to be under the hand and seal of the justice; should set forth the time and place of making, and the cause for which it is made; and should be directed to the constable, or other peace officer, or it may be to any private person by name. A general warrant to apprehend all persons suspected, without naming or particularly describing any person in special, is illegal and void for its uncertainty; for it is the duty of the magistrate, and ought not to be left to the officer, to judge of the ground of suspicion. Also a warrant to apprehend all persons guilty of such a crime, is no legal warrant; for the point upon which its authority rests, is a fact to be decided on a subsequent trial; namely, whether the person apprehended thereupon be guilty or not guilty. When a warrant is received by the officer, he is bound to execute it, so far as the jurisdiction of the magistrate and himself extends. A warrant from any of the justices of the court of king's bench extends over all the kingdom, and is tested or dated *England*: but a warrant of a justice of the peace in one county, must be backed, that is, signed, by a justice of another county, before it can be executed there. And a warrant for apprehending an English or a Scotch offender, may be indorsed in the opposite kingdom, and the offender carried back to that part of the united kingdom in which the offence was committed.

WARRANTY, WARRANTIA, in law, a promise, or covenant, by deed, made by the bargainer for himself and his heirs, to warrant and secure the bargainee and his heirs, against all men, for enjoying the thing agreed on or granted between them.

WARREN (Sir Peter), an admiral, distinguished by his virtue, learning, and undaunted courage, was descended from an ancient family in Ireland, and received a suitable education to qualify him for a command in the royal navy, in which he served for several years with great reputation; but the transaction which placed his great abilities in their full light, was the taking of Louisbourg in the year 1745, when he was appointed commodore of the British Squadron sent on that service. He joined the fleet of transports from Boston in Carlo-bay on the 25th of April, having under his command the *Superb* of 60, and the *Launceston* and *Eltham* of 40 guns; he was afterwards joined by several other men of war sent from England, and took possession of Louisbourg on the 17th of June. The French, exasperated at this loss, were constantly on the watch to re-

take it; and in 1747 fitted out a large fleet for that purpose, and at the same time another Squadron to prosecute their success in the East Indies. These Squadrons sailed at the same time; but the views of the French were rendered abortive by the gallant admiral Anson and Sir Peter Warren, who had been created rear-admiral, who with a large fleet of ships fell in with the French, defeated the whole fleet, and took the greatest part of the men of war. This was the last service Sir Peter rendered to his country as a commander in the British fleet; for a peace being concluded in the succeeding year, the fleet was laid up in the several harbours.

He was now chosen one of the representatives in parliament for Westminster; and in the midst of his popularity he paid a visit to Ireland, his native country, where he died of an inflammatory fever in 1752, sincerely lamented by all ranks of people; and an elegant monument of white marble was erected to his memory in Westminster abbey.

WARREN, is a franchise or place privileged by prescription or grant from the king, for the keeping of beasts and fowls of the warren; which are hares and coney, partridges, pheasants, and some add quails, woodcocks, and water-fowl, &c. These being *fera natura*, every one had a natural right to kill as he could: but upon the introduction of the forest laws at the Norman conquest, these animals being looked upon as royal game, and the sole property of our savage monarchs, this franchise of free-warren was invented to protect them, by giving the grantee a sole and exclusive power of killing such game, so far as his warren extended, on condition of his preventing other persons. A man therefore that has the franchise of warren, is in reality no more than a royal game-keeper: but no man, not even a lord of a manor, could by common law justify sporting on another's soil, or even on his own, unless he had the liberty of free warren. This franchise is almost fallen into disrepute since the new statutes for preserving the game; the name being now chiefly preserved in grounds that are set apart for breeding hares and rabbits. There are many instances of keen sportsmen in ancient times, who have sold their estates, and reserved the free-warren, or right of killing game, to themselves: by which means it comes to pass that a man and his heirs have sometimes free-warren over another's ground.

A warren may lie open; and there is no necessity of inclosing it as there is of a park. If any person offend in a free-warren, he is punishable by the common law, and by statute, 21 Edw. III. And if any one enter wrongfully into any warren, and chase, take, or kill, any coney without the consent of the owner, he shall forfeit treble damages, and suffer three months imprisonment, &c. by 22 and 23 Car. II. c. 25. When coney are on the soil of the party, he hath a property in them by reason of the possession, and action lies for killing them; but if they run out of the warren and eat up a neighbour's corn, the owner of the land may kill them, and no action will lie.

WARSAW, a large city of Poland, the capital of that country, and of the province of Masovia. It is built partly in a plain, and partly on a gentle ascent rising from the banks of the Vistula, which is about as broad as the Thames at Westminster, but very shallow in summer. This city and its suburbs occupy a vast extent of ground, and are supposed to contain 70,000 inhabitants, among whom are a great number of foreigners. The whole has a melancholy appearance, exhibiting the strong contrast of wealth and poverty, luxury and distress, which pervades every part of this unhappy country. The streets are spacious, but ill paved; the churches and public buildings are large and magnificent; the palaces of the nobility are numerous and splendid;

Washing-
ton.

did; but the greatest part of the houses, particularly in the suburbs, are mean and ill-constructed wooden hovels.—Warsaw is 160 miles south-east by south of Dantzic, 130 north-north-east of Cracow, and 300 north-east by north of Vienna. E. Long. 21. 6. N. Lat. 50. 14.

WART. See *SURGERY-Index*.

WARWICK, the capital of Warwickshire in England, and from which this county derives its name. It is very ancient, and supposed by Camden to be the place called by the Romans *Præsidium*, where the Dalmatian horse were posted. It stands on a rock of free-stone, of which all the public edifices in the town are built. At the Norman invasion it was a considerable place; and had many burghesses, of whom 12 were obliged by their tenure to accompany the king in his wars. It is supplied with water brought in pipes from springs half a mile from the town, besides what it derives from the wells within it made in the rock: and it is easily kept clean, by being situated upon a declivity. Four streets, from the four cardinal points of the compass, meet in the centre of the town. The principal public buildings are St Mary's, a very stately edifice, an hospital, a town-house of free-stone, three charity schools, and a noble bridge over the Avon. It has had several charters; but is governed at present by a mayor, 12 brethren, 24 burghesses, &c. It is a very handsome populous town, and gives title of earl to the family of the Greivilles. W. Long. 1. 36. N. Lat. 52. 20.

WASH, among distillers, the fermentable liquor used by the malt distillers. See *BREWERY*.

WASHING, in painting, is when a design, drawn with a pen or crayon, has some one colour laid over it with a pencil, as Indian ink, bistre, or the like, to make it appear the more natural, by adding the shadow of prominences, apertures, &c. and by imitating the particular matters whereof the thing is supposed to consist.

Thus they wash with a pale red, to imitate brick and tile; with a pale Indian blue, to imitate water and slate; with green, for trees and meadows; with saffron or French berries, for gold or brass; and with several colours for marbles.

WASHING of Ores, the purifying an ore of any metal, by means of water, from earths and stones, which would otherwise render it difficult of fusion.

WASHINGTON, a city of North America, now building for the metropolis of the United States. It is seated at the junction of the rivers Potomac and the Eastern Branch, extending about four miles up each, including a tract of territory scarcely to be exceeded, in point of convenience, salubrity, and beauty, by any in the world. This territory, which is called *Columbia*, lies partly in the state of Virginia, and partly in that of Maryland, and was ceded by these two states to the United States of America, and by them established to be the seat of government after the year 1800. It is divided into squares or grand divisions, by streets running due north, and south, and east, and west, which form the ground-work of the plan. However, from the Capitol, the president's house, and some of the important areas in the city, run diagonal streets, from one material object to another, which not only produce a variety of charming prospects, but remove the insipid sameness which renders some other great cities unpleasing. The great leading streets are all 160 feet wide, including a pavement of 10 feet, and a gravel walk of 30 feet planted with trees on each side, which will leave 80 feet of paved street for carriages. The rest of the streets are in general 110 feet wide, with a few only 90 feet, except North, South, and East Capitol Streets, which are 160 feet. The diagonal streets are named after the respective states composing the Union, while

those running north and south are, from the Capitol east. ward, named *East First Street, East Second Street, &c.* and those west of it are in the same manner called *West First Street, West Second Street, &c.* Those running east and west are from the Capitol northward named *North A Street, North B Street, &c.* and those south of it are called *South A Street, South B Street, &c.* The squares or divisions of the city amount to 1150. The rectangular squares generally contain from three to six acres, and are divided into lots of from 40 to 80 feet in front, and their depth from about 110 to 300 feet, according to the size of the square. The irregular divisions produced by the diagonal streets are some of them small, but generally in valuable situations. Their acute points are all to be cut off at 40 feet, so that no house in the city will have an acute corner. All the houses must be of brick or stone. The area for the Capitol (or house for the legislative bodies) is situated upon the most beautiful eminence in the city, about a mile from the Eastern Branch, and not much more from the Potomac, commanding a full view of every part of the city, as well as a considerable extent of the country around. The president's house will stand upon a rising ground, not far from the banks of the Potomac, possessing a delightful water prospect, with a commanding view of the Capitol, and some other material parts of the city.

The city being situated upon the great post road, exactly equidistant from the northern and southern extremities of the Union, and nearly so from the Atlantic Ocean to the river Ohio, upon the best navigation, and in the midst of the richest commercial territory in America, commanding the most extensive internal resources, is by far the most eligible situation for the residence of congress; and it is now pressing forward, by the public-spirited enterprise, not only of the people of the United States, but also of foreigners.

WASP, in zoology. See *VESPA*.

WATCH, in the art of war, a number of men posted at any passage, or a company of the guards who go on the patrol.

WATCH, in the navy, the space of time wherein one division of a ship's crew remains upon deck, to perform the necessary services, whilst the rest are relieved from duty, either when the vessel is under sail or at anchor.

The length of the sea-watch is not equal in the shipping of different nations. It is always kept four hours by our British seamen, if we except the dog-watch, between four and eight in the evening, that contains two reliefs, each of which are only two hours on deck. The intent of this is to change the period of the night-watch every 24 hours; so that the party watching from 8 till 12 in one night, shall watch from midnight till four in the morning on the succeeding one. In France the duration of the watch is extremely different, being in some places six hours, and in others seven or eight; and in Turkey and Barbary it is usually five or six hours.

A ship's company is usually classed into two parties; one of which is called the *starboard* and the other the *larboard* watch. It is, however, occasionally separated into three divisions, as in a road or in particular voyages.

In a ship of war the watch is generally commanded by a lieutenant, and in merchant-ships by one of the mates; so that if there are four mates in the latter, there are two in each watch; the first and third being in the larboard, and the second and fourth in the starboard watch: but in the navy, the officers who command the watch usually divide themselves into three parties, in order to lighten their duty.

WATCH, is also used for a small portable movement, or machine, for the measuring of time; having its motion regulated by a spiral spring.

Watches, strictly taken, are all such movements as show the parts of time; as clocks are such as publish it, by striking on a bell, &c. But commonly the name *watch* is appropriated to such as are carried in the pocket; and *clock* to the large movements, whether they strike the hour or not. See *CLOCK*.

The invention of spring or pocket-watches belongs to the present age. It is true, we find mention made of a watch presented to Charles V. in the history of that prince: but this, in all probability, was no more than a kind of clock to be set on a table, some resemblance whereof we have still remaining in the ancient pieces made before the year 1670. There was also a story of a watch having been discovered in Scotland belonging to king Robert Bruce; but this we believe has turned out altogether apocryphal. The glory of this very useful invention lies between Dr Hooke and M. Huyghens; but to which of them it properly belongs, has been greatly disputed; the English ascribing it to the former, and the French, Dutch, &c. to the latter. Mr Derham, in his Artificial Clockmaker, says roundly, that Dr Hooke was the inventor; and adds, that he contrived various ways of regulation. One way was with a loadstone: Another with a tender straight spring, one end whereof played backwards and forwards with the balance; so that the balance was to the spring as the bob to a pendulum, and the spring as the rod thereof: A third method was with two balances, of which there were divers sorts; some having a spiral spring to the balance for a regulator, and others without. But the way that prevailed, and which continues in mode, was with one balance, and one spring running round the upper part of the verge thereof: Though this has a disadvantage, which those with two springs, &c. were free from; in that a sudden jerk, or confused shake, will alter its vibrations, and put it in an unusual hurry.

The time of these inventions was about the year 1658; as appears, among other evidences, from an inscription on one of the double balance watches presented to king Charles II. viz. Rob. Hooke *inven.* 1658. T. Tompion *fecit.* 1675. The invention presently got into reputation, both at home and abroad; and two of them were sent for by the dauphin of France. Soon after this, M. Huyghens's watch with a spiral spring got abroad, and made a great noise in England, as if the longitude could be found by it. It is certain, however, that his invention was later than the year 1673, when his book *de Horol. Oscillat.* was published; wherein he has not one word of this, though he has of several other contrivances in the same way.

One of these the lord Brouncker sent for out of France, where M. Huyghens had got a patent for them. This watch agreed with Dr Hooke's in the application of the spring to the balance; only M. Huyghens's had a longer spiral spring, and the pulses and beats were much slower. The balance, instead of turning quite round, as Dr Hooke's, turns several rounds every vibration.

Mr Derham suggests, that he has reason to doubt M. Huyghens's fancy first was set to work by some intelligence he might have of Dr Hooke's invention from Mr Oldenburg, or some other of his correspondents in England; and this, notwithstanding Mr Oldenworth's attempt to vindicate himself in the Philosophical Transactions, appears to be the truth (A). Huyghens invented divers other kinds of watches, some of them without any string or chain at all; which he called, particularly, *pendulum watches*.

Striking WATCHES are such as, besides the proper watch-part for measuring of time, have a clock part for striking the hours, &c.

Repeating WATCHES, are such as by pulling a string, &c. repeat the hour, quarter, or minute, at any time of the day

5 1 2

or

(A) To expect perfection in a work of this extent would be unreasonable, and we trust to the candour of our readers for their acceptance of our best endeavours: we hold ourselves much obliged to them for their communications of every remark which may enable us to render the Encyclopædia Britannica more worthy of that most encouraging reception which it has met with from the Public. To the regular series of articles, the present Editor had once reason to believe that a Supplement was to be annexed, which should include not only those additions which have been made to the circle of the sciences during the progress of the work, but likewise such articles as he or his predecessor had, through their unremitting occupation or their ignorance, suffered to escape their notice. In that Supplement he would have corrected all such errors or mistakes in the work as might have been discovered by himself or pointed out to him by his Correspondents. But he is no Proprietor, and cannot announce the publication of a Supplement but as an event of great uncertainty. He is therefore much obliged to his highly respected friend and correspondent who has put it in his power at present to do justice to the memory of Dr Robert Hooke; one of the greatest ornaments of the Royal Society of London during the time of its infant state and juvenile vigour, and one of the most extensive and inventive geniuses that the world has ever seen.

In the article *HAUTEFEUILLE*, we ascribe to that author the invention of the regulating or balance spring of a watch, by which its motion is made as truly equable as by a pendulum. This is verified by the watches of Harrison, Arnold, and others, which do not deviate from equable motion above one second in several days. That the importance of this is acknowledged by the intelligent Public, is evident from the serious and repeated deliberations of the British Senate, and the high rewards which it has given to the makers of such watches; and we trust that this will appear to such of our readers as are not so much interested in mechanical performances a sufficient excuse for our anxiety to give the honour of the invention to its right owner. We had collected from our searches that Mr Huyghens had discovered, by his analysis of pendulous motions, what kind of motion would be produced by any kind of varying force, and that a force varying in the proportion of its distance from the place of rest would produce isochronous vibrations, whatever might be their extent; and had made experiments on the force of springs, and found them to vary according to this very law. In consequence of this, he saw that a balance-watch might be made to answer the same end with his cycloidal pendulum-clock, which he had been for several years trying to fit for the discovery of the longitude of a ship at sea, under the protection of the States of Holland and the court of France, having obtained a patent monopoly from the States and from Louis XIV. When, after repeated disappointments, he introduced his proposed watches, with sanguine hopes of their performance, but before any trial, and applied for such an extension of his patent as should also comprehend a balance regulated by a spring, he was opposed by the watch-makers. They had willingly acquiesced in his exclusive right to the pendulum-clock, which was entirely his own demerit; but they could not help considering this extension of his patent as an encroachment on a common which they had possessed from time immemorial. The opposition was general both in

Holland

Watch.

or night.—This repetition was the invention of Mr Barlow, and first put in practice by him in larger movements or clocks about the year 1676. The contrivance immediately set the other artists to work, who soon contrived divers ways of effecting the same. But its application to pocket-watches was not known before king James the Second's reign; when the ingenious inventor above-mentioned, having directed Mr Thompson to make a repeating watch, was soliciting a patent for the same. The talk of a patent engaged Mr Quare to reforme the thoughts of a like contrivance, which he had had in view some years before: he now effected it; and being pressed to endeavour to prevent Mr Barlow's patent, a watch of each kind was produced before

the king and council; upon trial of which, the preference was given to Mr Quare's. The difference between them was, that Barlow's was made to repeat by pushing in two pieces on each side the watch-box; one of which repeated the hour, and the other the quarter: whereas Quare's was made to repeat by a pin that stuck out near the pendant, which being thrust in (as now it is done by thrusting in the pendant itself), repeated both the hour and quarter with the same thrust.

Of the Mechanism of a Watch, properly so called. Watches, as well as clocks, are composed of wheels and pinions, and a regulator to direct the quickness or slowness of the wheels, and of a spring which communicates motion to the

Holland and in France, and naturally came to the knowledge of Mr Hautefeuille. This person was conscious of a double right to oppose this encroachment, having also, though perhaps empirically, and without principle, discovered that a spring, applied to the balance of a watch, produced a surprising equability of vibration; and hoped by its means to produce a perfect isochronism. By Mr Hautefeuille's opposition the effect of the French patent was stopped for want of registration. The Dutch patent was however expedited, and trials were made. But their result was unfavourable; many things were wanting besides the true adjustment of the regulating power of the balance-spring. Scientific mechanics was then in its infancy, Galileo was dead, Newton was but beginning his glorious career; Huyghens therefore had few assistants.

The Royal Society of London was just founded, and Charles II. or his brother the duke of York, saw, *like a prince*, how conducive their labours would be to public prosperity, and particularly to the improvement of navigation. The king therefore enjoined them to turn much of their attention to this object: he established the Royal Observatory at Greenwich for this express purpose; and the parliament held out encouragement for the discovery of the longitude. It was natural therefore for Mr Huyghens to look to this quarter for encouragement; and if any one will take the pains to compare the dates of Mr Huyghens's mathematical labours, after his dissertation on the pendulum, and his correspondence with the British literati, till he was elected member of the Royal Society, his *private* correspondence afterward with Mr Oldenburgh, a German, their secretary, and his public correspondence with him as secretary of the Society, he will observe the operation of something more than scientific zeal.

This correspondence, however, did not answer Mr Huyghens's hopes; for it informed him that the ground had been preoccupied by Mr Hooke, who had long before discovered, that a spring properly applied to a watch-balance would produce isochronous vibrations, and had also long ago applied for a Royal patent for the monopoly. The history of this application is curious, as a mere matter of anecdote; and it is instructive, while it is humiliating to human vanity, showing us, that even in the greatest characters, genius and talents, and noble and undoubted virtues, may exist along with some of our less honourable propensities, and cannot altogether hinder their operation. There never was a time in which it was more proper that every one of us should have a monitor, who should sometimes call out aloud to us, "Remember that thou art a man," than the present, when fanatic vanity, under the false and abused name of *philosophy*, is waging war with every thing that is good or true, and threatens to plunge the cultivated portions of the human race into their former barbarism, with the horrid addition of the habits of savage atrocity; while the voice of religion, which would call us together as the children of one parent, is stifled amidst the yells of brother fiends. We hope for indulgence, then, while we endeavour, in a few words, to make the history of this invention as clear as can be expected in a subject which does not so sensibly interest the public in general, and after such a long interval of time.

Mr Hooke, from his infancy, had a strong predilection for mechanics; he had also a strong propensity to system-making; and, from his first years of serious occupations, entertained a notion, that every thing might be formed into a system, and that nothing could be prosecuted with any well-founded prospect of improvement unless it was so treated. His amazingly comprehensive genius grasped at every thing which came under his observation; and he immediately began to form a system about it.—His writings are full of scraps of such systematic views; many of them, it must be acknowledged, hasty, inaccurate, and futile, but still systematical. He called them algebras, and considered them as having a sort of inventive power, or rather as means of discovering things unknown by a process somewhat similar to that art. He valued himself highly on account of this view of science, which he thought peculiar to himself; and he frequently speaks of others, even of the most eminent, as childishly contenting themselves with partial views of the corners of things. He was likewise very apt to consider other inventors as encroachers on his systems, which he held as a kind of property, being seriously determined to prosecute them all in their turn, and never recollecting that any new object immediately called him off, and engaged him for a while in the most eager pursuit. His algebras had already given him many signal helps; and he had no doubt of their carrying him through in every investigation. Stimulated by this overfond expectation, when a discovery was mentioned to him he was too apt to think and to say, that he had long ago invented the same thing; when the truth probably was, that the course of his systematic thoughts on the subjects with which it was connected had really suggested it to him, with such vivacity, or with such notions of its importance, as to make him set it down in his register in its own systematic place (for this was his constant practice, worthy of such a genius, and of immense service to all inquisitive men). But it was put out of his mind by some new object of pursuit. We, at this time, can hardly conceive the ardour with which every thing was treated in those youthful days of scientific novelty.

His favourite algebra, of which he frequently speaks as an invaluable treasure, and the source of all his reputation, was his Mechanical Algebra or Method of Mechanic Invention. He says, that no question in mechanics could be proposed to him, but he could quickly tell whether it were possible to solve it, and could get into the proper track for the solution.

Unfortunately

the whole machine. But the regulator and spring of a watch are vastly inferior to the weight and pendulum of a clock, neither of which can be employed in watches. In place of a pendulum, therefore, we are obliged to use a balance (fig. 1.) to regulate the motion of a watch; and a spring (fig. 2.) which serves in place of a weight, to give motion to the wheels and balance.

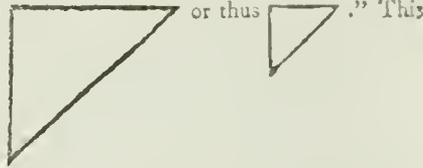

The wheels of a watch, like those of a clock, are placed in a frame formed of two plates and four pillars. Fig. 3. represents the inside of a watch, a ter the plate (fig. 4.) is taken off. A is the barrel which contains the spring (fig. 2.); the chain is rolled about the barrel, with one end of it fixed to the barrel A (fig. 5.), and the other to the fusee B.

When a watch is wound up, the chain which was upon the barrel winds about the fusee, and by this means the spring is stretched; for the interior end of the spring is fixed by a hook to the immovable axis, about which the barrel revolves; the exterior end of the spring is fixed to the inside of the barrel, which turns upon an axis. It is therefore easy to perceive how the spring extends itself, and how its elasticity forces the barrel to turn round, and consequently obliges the chain which is upon the fusee to unfold and turn the fusee; the motion of the fusee is communicated to the wheel C (fig. 5.); then, by means of the teeth, to the pinion *c*, which carries the wheel D; then to the pinion *d*, which carries the wheel E; then to the pinion *e*, which

Watch.

Unfortunately this perished in the burning of Gresham College, where Mr Hooke had apartments from the Royal Society; and he does not seem to have replaced it. It was perhaps, like the rest, nothing more than scraps. The Correspondent who favours us with these observations saw, in 1768, many papers of Mr Hooke's writings in the Society's archives, which had evidently been rescued from the flames, and had been in the possession of Mr Waller; part of which he published, and would have given more had he lived. Many of the leaves were scraps, perhaps single lines; many had dates; many of them were such as would be fragments of this mechanical algebra. Mr Hooke positively says, that it was by this system that he discovered the regulating power of a spring. And this brings us to the subject in hand, to which we hope the foregoing observations will not be thought too long a preface.

In 1655 he was admitted into the INVISIBLE SOCIETY at Oxford, and was particularly patronised by Dr Ward, afterwards bishop of Salisbury, who instructed him in astronomy, and strongly recommended to his mechanical genius the discovery of some method of maintaining the vibrations of a pendulum, as of immense service to the astronomer. This Hooke accomplished immediately, and thought of using pendulum clocks for discovering the longitude at sea; and his method of mechanic inventions quickly led him, he says, to the discovery of the regulating power of springs as equivalent (nay, he says, superior) to that of gravity. This is remarkable; for it appears that he had at that time mathematics enough to inform him, that nothing would produce isochronous vibrations but an accelerative force proportional to the space to be passed through, a truth neither obvious nor easily come at; and that the accelerative action of gravity on a common pendulum was not exactly in this proportion: but he did not then know the mechanical properties of the cycloid, a discovery reserved to do honour to Mr Huyghens. Our Correspondent farther informs us, that he recollects seeing, among the scraps of Mr Hooke's writing, words nearly to the following purpose: "To produce a translation of a moveable thus ——— or thus ——— in the same time, requires a pressing power thus will evidently appear to be a hasty expression of a force as the distance to be run through. He had found by experiments, made probably with other views, that the force of a spring was proportional to its deviation from its quiescent shape, and this whatever was its shape. Of this truth he now saw the value, and marked it in his register, and gave it to his friends, agreeably to the custom of the times, in the form of a cipher *ce, iii, no, sss, tt, uu*; which was afterwards explained "*Ut tensio, sic vis.*"

Mr Boyle was then his chief patron, and to him he communicated his scheme of measuring time accurately by a balance-watch regulated by a spring; and showed him watches so constructed, which performed with surprising accuracy. Immediately after the Restoration, Mr Boyle acquainted Lord Brouncker and Sir Robert Moray, the most eminent gentlemen of the age for mathematical learning, and for natural knowledge in general, with Mr Hooke's discovery and scheme; and those gentlemen encouraged him to apply for a patent, and even drew up a form for an act of parliament, to give him a profit on his invention by a duty on shipping. This draught was shown to the king, and he granted a warrant for a patent to Mr Hooke for 14 years; which warrant was in the possession of Mr Waller.

It appears that these gentlemen were so sensible of the merits of the invention, and so confident of its success, that they associated themselves with Dr Hooke in the prosecution of it. But in what respect they were to contribute, besides their influence in procuring the patent and the act of parliament, does not appear. There remained, however, in Mr Waller's possession several scrolls and drafts of a mutual agreement between them to this effect: In one of them it was agreed, that if the profits should exceed L. 6000, Mr Hooke should have $\frac{1}{2}$ ths of the overplus; if it should be only L. 4000, he should have $\frac{2}{3}$ ds, &c. they having the rest; and that Dr Hooke should be declared the author and inventor. It is probable that they were to advance the money necessary for carrying on the trade of watchmaking.—Many alterations were made in the terms of agreement; and it appears, that before any thing definitive was done, Hooke was dissatisfied, because they insisted, that if they or any other person should fall on any way of improving on these principles, they should enjoy the benefit of it during the currency of the patent. This he flatly refused; saying, that it was *facile inventis addere*. It is probable that his manner of refusal, which never was gracious or polite, might offend persons of their rank, and contribute to put an end to the whole affair; for it never went farther, and Hooke became much more retentive and close than formerly.

But while things were on a friendly footing, there occurred sufficient proofs of Dr Hooke's being the author of the invention, and that even Mr Huyghens could hardly fail of knowing something of it when he was in England in 1663, ten or eleven years before he published his claim, and even before he had analysed the motion of pendulous bodies. In page 247. of the Society's Register, in 1667, mention is made of Hooke's watches for the pocket, where the motion is regulated by springs. Now Hooke, in his first watches, employed two opposite springs, straight, and acting on the balance

which carries the wheel F; then to the pinion *f*, upon which is the balance-wheel G, whose pivot runs in the pieces A called the *potance*, and B called a *follower*, which are fixed on the plate fig. 4. This plate, of which only a part is represented, is applied to that of fig. 3. in such a manner that the pivots of the wheels enter into holes made in the plate fig. 3. Thus the impressed force of the spring is communicated to the wheels: and the pinion *f* being then connected to the wheel F, obliges it to turn (fig. 5.) This wheel acts upon the palettes of the verge 1, 2, (fig. 1.), the axis of which carries the balance HH, (fig. 1.) The pivot I, in the end of the verge, enters into the hole *c* in the potance A (fig. 4.) In this figure the palettes are represented; but the balance is on the other side of the plate, as may be seen in fig. 6. The pivot 3 of the balance enters into a hole of the cock BC (fig. 7.), a perspective view of which is represented in fig. 8. Thus the balance turns between the cock and the potance *c* (fig. 4.), as in a kind of cage. The action of the balance-wheel upon the palettes 1, 2 (fig. 1.), is the same with what we have described with regard to the same wheel in the clock; *i. e.* in a watch, the balance-wheel obliges the balance to vibrate backwards and forwards like a pendulum. At each vibration of the balance a palette allows a tooth of the balance-wheel to escape; so that the quickness of the motion of the wheels is entirely determined by the quickness of the vibrations of the balance; and these vibrations of the balance and motion of the wheels are produced by the action of the spring.

But the quickness or slowness of the vibrations of the balance depend not solely upon the action of the great spring, but chiefly upon the action of the spring *a, b, c*, called the *spiral spring* (fig. 9.), situated under the balance H, and represented in perspective (fig. 6.) The exterior end of the spiral is fixed to the pin *a*, (fig. 9.) This pin is applied near the plate in *a*, (fig. 6.); the interior end of the spiral is fixed by a peg to the centre of the balance. Hence if the balance is turned upon itself, the plates remaining immovable, the spring will extend itself, and make the balance perform one revolution. Now, after the spiral is thus extended, if the balance be left to itself, the elasticity of the spiral will bring back the balance, and in this manner the alternate vibrations of the balance are produced.

In fig. 5. all the wheels above described are represented in such a manner, that you may easily perceive at first sight

how the motion is communicated from the barrel to the balance.

In fig. 10. are represented the wheels under the dial-plate by which the hands are moved. The pinion *a* is adjusted to the force of the prolonged pivot of the wheel D (fig. 5.), and is called a *canon pinion*. This wheel revolves in an hour. The end of the axis of the pinion *a*, upon which the minute-hand is fixed, is square; the pinion (fig. 10.) is indented into the wheel *b*, which is carried by the pinion *a*. Fig. 11. is a wheel fixed upon a barrel, into the cavity of which the pinion *a* enters, and upon which it turns freely. This wheel revolves in 12 hours, and carries along with it the hour-hand. For a full account of the principles upon which watches and all time-keepers are constructed, we must refer our readers to a short treatise, entitled *Thoughts on the Means of improving Watches*, by Thomas Mudge.

WATCH-glasses, in a ship, are glasses employed to measure the period of the watch, or to divide it into any number of equal parts, as hours, half-hours, &c. so that the several stations therein may be regularly kept and relieved, as at the helm, pump, look-out, &c.

WATCHING, in medicine, is when the patient cannot sleep. In fevers it is a dangerous symptom, and if long continued ends in a delirium.

WATER, a well known fluid, diffused through the atmosphere, and over the surface of the globe, and abounding in a certain proportion in animals, vegetables, and minerals.

The uses of water are so universally known, that it would be superfluous to enumerate them in this article. It is essential to animal and vegetable life; it makes easy the intercourse between the most distant regions of the world; and it is one of the most useful powers in the mechanic arts. It is often found combined with various substances, and is then frequently beneficial in curing or alleviating diseases.

Those properties of water which fit it for answering mechanical purposes are explained in other articles of this Work (see **HYDROSTATICS**, **PNEUMATICS**, n^o 3. **RESISTANCE**, and **RIVERS**); but it still remains for us to give an account of the late celebrated discovery of the composition of water, and the various substances which are often found chemically united with it.

The ancient philosophers considered water as one of the four elements. During the age of the alchymists, when it was believed that different substances could be converted into gold, it was also an opinion, adopted by many, that water could be changed into earth. Even so late as the time of Mr Boyle

stance by a silk fibre rolled round the cylindric axis of the balance. Mr Hooke, long after this, complained to the Society of Mr Oldenburgh's communicating this and other things to Huyghens, with whom he had an intimate correspondence. In 1665 Sir Robert Moray wrote a letter to Mr Oldenburgh, presuming, from his intimacy with Mr Huyghens, that he would know how soon his watches would be ready, and desired him to ask Mr Huyghens, "Whether he did not apply a spring to the axis of the balance?" and if he should say any thing to that purpose, then to tell him what Hooke had done in that way, and that he intended more. *N. B.* Before this time the treaty had been dropped, and there appeared to Sir Robert no farther need of concealment.

From these and other facts that might be produced, we think it most evident that Mr Hooke invented the regulating spring of a watch, by which it is made perfectly adequate to the purpose of finding the longitude at sea; that he invented it eight or ten years before Mr Huyghens thought of such a thing, and fifteen years before he published it in the *Journal des Sçavans* in 1674.

Our readers cannot fail of making some remarks on this anecdote, which will perhaps extenuate a little Mr Hooke's morose behaviour, and explain, and perhaps excuse, his disposition to boast of his own inventions and arrogate those of others. If any of the expressions in the article allotted to his name should have made too unfavourable an impression, this note may help to soften it. We do not think that it can be inferred from those facts that either Hautereuille or Huyghens purloined Hooke's invention. The one might fall upon it in the course of his many experiments; and the other, from his mathematical discoveries of the requisites for isochronous vibrations, might be induced to try whether springs afforded such a force. But there can remain no doubt but that Hooke made the discovery LIKE A PHILOSOPHER. If to this Work any Supplement shall be given by the present Editor, he will endeavour still farther to wipe away the obloquy which has been cast upon the memory of Dr Hooke for his arrogance in claiming the merit of inventions supposed to be the property of others.

Boyle this sentiment was not laid aside. He relates, that a friend of his, by distilling a quantity of water an hundred times, found at length that he had got six-tenths of the first quantity in earth: whence he concludes, that the whole water, by further prosecuting the operation, might be converted into earth. Others have made experiments to the same purpose, and seemingly with the same success; but the deception is now found out. Water has the power of corroding the hardest bodies, even glass itself, by long digestion, especially when assisted by heat; and hence those who have made the experiments just mentioned have been themselves deceived, by supposing the earth which really came from the containing vessel to come from the water.

Margraaf made several experiments to determine whether water be transmutable into earth, and found that after every distillation a sediment was left. Lavoisier repeated Margraaf's experiments, and gave the explanation which we alluded to, that the sediment consisted of portions of the glass separated by the water. Dr Black, in the valuable course of lectures which he has for many years delivered, with so much honour to himself, and so much to the advancement of the science of chemistry, goes still farther: he ingeniously supposes, that the alkali, which is an essential ingredient in the composition of glass, unites with the water, and makes the glass swell, and thus occasions small portions of it to be detached.

Historical Account of the Discovery of the Composition of Water.

THAT water is not a simple but a compound substance, consisting of a mixture of vital and inflammable air, is one of the most astonishing and important discoveries which has been made since the origin of chemistry, or indeed since the origin of science. The history of this curious and interesting discovery we shall trace back with as much precision and impartiality as possible to the first hints which were thrown out upon the subject, and endeavour at the same time to assign to all who have contributed to the discovery the merit to which they are respectively intitled.

The first thing that led chemists to make experiments concerning the composition of water, was a letter which Mr John Warltire, lecturer in natural philosophy, wrote to Dr Priestley, dated Birmingham 18th April 1781, and published in the Appendix to the 5th volume of Dr Priestley's *Experiments and Observations*. This gentleman had long entertained an opinion that the question "whether heat be a heavy body," might be determined by burning inflammable air mixed with atmospherical air. For some time he was deterred from trying the experiment, from an apprehension that the consequences of passing the electrical spark through so combustible a mixture might be attended with danger; but at length, being encouraged by Dr Priestley, he prepared an apparatus for the purpose. He got a copper ball weighing 14 oz. and sufficient to contain three wine pints, with a screw stopper adapted to it, so that no air could escape. When he filled this ball with inflammable and common air, and made the electric spark to pass thro' it, a loss of weight was observed, upon an average, about two grains. When the same experiment was made in close glass vessels, the inside of the glass, though clean and dry before the operation, became immediately wet with dew, and was lined with a sooty substance. When Mr Warltire saw the moisture, he said to Dr Priestley, that it confirmed an opinion which he had long entertained, that common air deposits its moisture when it is phlogisticated. After this experiment had been repeated by Dr Priestley and Mr Warltire in company, they next fired a mixture of vital and inflammable air; but the only effects which they observed

were, that the light was much more intense, and the heat much greater.

During the same year, and after the publication of the volume of Dr Priestley's works, referred to above, Mr Cavendish repeated the experiments of Mr Warltire; but though the vessel which he used held 24,000 grains of water, and though the experiment was repeated several times with common and inflammable air, he could never perceive a loss of weight of more than one-fifth of a grain, and commonly none at all. In all these experiments Mr Cavendish did not perceive the least sooty matter; but the inside of the glass globe became dewy, as Mr Warltire had observed. The inflammable air was procured from zinc.

That he might examine the nature of the dew, he burned 500,000 grain measures of inflammable air with two and a half times that quantity of common air, and the burned air was made to pass through a glass cylinder eight feet long, and three quarters of an inch diameter, in order to deposit the dew. These two kinds of air were mixed and set on fire by a lighted candle. In a short time 135 grains of water were condensed in the cylinder, which had no taste nor smell, and which left no sensible sediment when evaporated to dryness; neither did it yield any pungent smell during the evaporation: in short, it seemed pure water. From this experiment Mr Cavendish concluded, that when inflammable and common air are exploded in a proper proportion, almost all the inflammable air, and near one-fifth of the common air, lose their elasticity, and are condensed into dew; which, when examined, is found to be pure water.

He wished next to examine the effect produced by firing a mixture of vital and inflammable air. He took a glass globe holding 8800 grain measures, furnished with a brass cock, and an apparatus for firing air by electricity. The globe was exhausted of its air by an air-pump, and then a mixture of 19,500 grain measures of dephlogisticated air, and 37,000 of inflammable air, was conveyed successively from a glass jar, inverted in water, into the globe, and there fired by electricity. At the end of the experiment, when the whole air was consumed, a condensed liquor was found in the globe, weighing about 30 grains, which was sensibly acid to the taste; and, by saturation with fixed alkali and evaporation, yielded near two grains of nitre. This product of nitre must have been occasioned by a mixture of azotic gas, which had combined with part of the oxygen, or dephlogisticated air; which are now well known to be the component parts of the nitric acid. These experiments, Mr Cavendish informs us, were made in 1781.

Mr Cavendish having mentioned these experiments to Dr Priestley, that gentleman made a course of experiments in order to investigate the same subject; an account of which is published in the *Philosophical Transactions* for 1783, and by Dr in the last volume of his *Experiments*. Having formerly observed several remarkable changes in fluid substances, in consequence of long exposure to heat in glass vessels hermetically sealed, Dr Priestley formed a design of exposing all kinds of solid substances to great heats in close vessels. As many substances consist of parts so volatile as to fly off before attaining any considerable degree of heat in the usual pressure of the atmosphere, he imagined that if the same substances were compelled to bear great heats under a greater pressure, they might assume new forms, and undergo remarkable changes. Happening to mention these ideas to Mr Watt, the ingenious inventor of the steam-engine, Mr Watt mentioned a similar idea of his, that it might be possible to convert water or steam into permanent air.

WATER

Mr Cavendish

repeated

the experiments

of Mr Warltire;

but though

the vessel which

he used held

24,000 grains

of water,

and though

the experiment

was repeated

several times

with common

and inflammable

air, he could

never perceive

a loss of weight

of more than

one-fifth of a

grain, and com-

monly none

at all. In all

these experi-

ments Mr

Cavendish

did not per-

ceive the

least sooty

matter; but

the inside

of the glass

globe be-

came dewy,

as Mr

Warltire

had ob-

served. The

inflammable

air was

procured

from zinc.

That he

might exam-

ine the na-

ture of the

dew, he

burned

500,000

grain mea-

sures of

inflammable

air with

two and a

half times

that quan-

tity of com-

mon air, and

the burned

air was

made to

pass thro-

ugh a glass

cylinder

eight feet

long, and

three quar-

ters of an

inch diam-

eter, in or-

der to de-

posit the

dew. These

two kinds

of air were

mixed and

set on fire

by a light-

ed candle.

In a short

time 135

grains of

water were

condensed

in the cy-

linder, which

had no taste

nor smell,

and which

left no sen-

sible sedi-

ment when

evaporated

to dryness;

neither did

it yield any

pungent

smell dur-

ing the e-

vaporation:

in short, it

seemed pure

water. From

this experi-

ment Mr

Cavendish

concluded,

that when

inflam-

mable and

common

air are ex-

ploded in

a proper

proportion,

almost all

the inflam-

mable air,

and near

one-fifth

of the com-

mon air, lose

their elas-

ticity, and

are con-

densed into

dew; which,

when ex-

amined, is

found to

be pure

water.

He wished

next to

examine

the effect

produced

by firing

a mixture

of vital

and inflam-

mable air.

He took

a glass

globe hold-

ing 8800

grain mea-

sures, fur-

nished with

a brass

cock, and

an appa-

ratus for

firing air

by electri-

city. The

globe was

exhausted

of its air

by an air-

pump, and

then a

mixture

of 19,500

grain mea-

sures of

dephlogis-

ticated air,

and 37,000

of inflam-

mable air,

was con-

veyed suc-

cessively

from a

glass jar,

inverted

in water,

into the

globe, and

there

fired by

electricity.

At the end

of the ex-

periment,

when the

whole air

was con-

sumed, a

condensed

liquor was

found in

the globe,

weighing

about 30

grains, which

was sensibly

acid to the

taste; and,

by satur-

ation with

fixed alkali

and e-

vaporated,

yielded

near two

grains of

nitre. This

product

of nitre

must have

been occa-

sioned by

a mixture

of azotic

gas, which

had com-

bined with

part of the

oxygen,

or dephlog-

isticated

air; which

are now

well known

to be the

component

parts of the

nitric acid.

These ex-

periments,

Mr Caven-

dish in-

forms us,

were made

in 1781.

Mr Caven-

dish hav-

ing men-

tioned

these ex-

periments

to Dr

Priestley,

that gen-

tleman

made a

course

of experi-

ments in

order to

investi-

gate the

same sub-

ject; an

account

of which

is pub-

lished in

the *Phil-**osophical**Transac-**tions* for

1783, and

by Dr

in the

last vol-

ume of

his *Ex-**periments*.

Having

formerly

observed

several

remark-

able

changes

in fluid

substan-

ces, in

con-

sequence

of long

exposure

to heat

in glass

vessels

her-

metically

sealed,

Dr

Priestley

formed

a design

of expo-

sing all

kinds of

solid sub-

Water. For many years before this period, Mr Watt tells us he had entertained an opinion, that air was a modification of water, which was originally founded on the facts, that in most cases wherein air was actually made (which should be distinguished from those wherein it is only extricated from substances containing it in their pores, or otherwise united to them in the state of air), the substances were such as were known to contain water as one of their constituent parts; yet no water was obtained in the processes, except what was known only to be loosely connected with them, such as the water of the crystallization of salts. This opinion arose from a discovery, that the latent heat contained in steam diminished in proportion as the sensible heat of the water from which it was produced increased. In other words, the denser the steam was, the less latent heat it contained.

Account of Mr Watt's theory. Phil. Trans. for 1784, p. 335.

Having been informed by Dr Priestley of the result of the experiment of firing a mixture of dephlogisticated and inflammable air, Mr Watt was enabled to form the very theory which has been since demonstrated to be true. "Let us consider (says he) what obviously happens in the case of the deflagration of the inflammable and dephlogisticated air. These two kinds of air unite with violence, they become red hot, and upon cooling totally disappear. When the vessel is cooled, a quantity of water is found in it equal to the weight of the air employed. The water is then the only remaining product of the process; and water, light, and heat, are all the products, unless there be some other matter set free which escapes our senses. Are we not then authorized to conclude, that water is composed of dephlogisticated air and phlogiston deprived of part of their latent or elementary heat; that dephlogisticated or pure air is composed of water deprived of its phlogiston and united to elementary heat and light; and that the latter are contained in it in a latent state, so as not to be sensible to the thermometer or to the eye; and if light be only a modification of heat, or a circumstance attending it, or a component part of the inflammable air, then pure or dephlogisticated air is composed of water deprived of its phlogiston and united to elementary heat?"

Phil. Trans. for 1784, & Idées sur la Météor. par J. A. De Luc, tom. ii. p. 213.

We have said that the theory of Mr Watt is now demonstrated to be true. To this assertion an objection may be raised from the language in which he states his theory; for he explains it by using the word *phlogiston*, a word which is now exploded from philosophy as the name of an imaginary substance. But it is sufficient to reply, that Mr Watt uses the word *phlogiston* as synonymous with inflammable air. It may be proper also to add, that the passage quoted above was contained in a letter from Mr Watt to Dr Priestley, dated the 26th of April 1783.

Most of the experiments hitherto made favoured the conclusion which Mr Watt had drawn; but so many difficulties occurred to Mr Cavendish and Dr Priestley, that they seemed to hesitate about the theory. Dr Priestley in particular, after consideration, declared against it; while Mr Cavendish only waited till the difficulties should be removed. In the mean time experiments were made in a different quarter, which gave the most incontestable proofs of the truth of the theory.

8 Which is established by experiments at Paris. Idées sur la Météor. par De Luc, tom. ii. part iii. chap. iv.

M. de Luc had gone to Paris in January 1783. During his residence there, he received a letter from Dr Priestley, announcing the result of his experiments concerning the conversion of water into air. M. de Luc immediately communicated the contents of this letter to several members of the Academy of Sciences. But the difficulties which had occurred to Dr Priestley prevented them from acquiescing in Mr Watt's theory. In the month of June following, Dr Blegden, who was well acquainted with all the experiments

both of Mr Cavendish and of Dr Priestley, and of the opinions of Mr Watt, made a journey to Paris, in which he had an opportunity of conversing on this subject with the same gentlemen of the Academy to whom M. de Luc had formerly imparted the experiments of Dr Priestley. Notwithstanding the additional facts which he was enabled to lay before them, he found them averse from admitting the theory. They supposed that the water collected after the combustion of the two kinds of air had been dissolved in them before. As the question depended upon the proof of a fact, they resolved however to make the proper experiments for examining it. The celebrated Lavoisier took this experiment upon himself. It was made on the 24th of June in the presence of Dr Blegden and many gentlemen of the academy; and the success was as complete as the most sanguine imagination could have conceived. It was repeated by Messrs Monge and Meunier, and the same result was found. The composition of water was now therefore put beyond doubt, and is now almost universally received as an unquestionable fact.

As we wish upon all occasions to ascribe to all eminent men the honour which they deserve, we should willingly estimate the comparative merit of those philosophers who were most active in this discovery; but though we feel ourselves disposed to be altogether impartial, it is attended with so many difficulties, that we will not presume to affirm that our opinions are formed with perfect accuracy. With respect to Mr Watt, we think it appears that he was the first person who formed the true theory. He had for many years before thought it probable, that if the latent heat of steam could be wholly converted into sensible heat by a great increase of heat, the steam might suffer some remarkable change, such as into permanent air. And no sooner had he heard of the deflagration of oxygenous and hydrogenous gas by Dr Priestley, than he formed this theory.

Asten the m of the conce in thi cover Merit Mr V Phil. for 17 335

Mr Cavendish had the merit of making a proper use of Dr Priestley's account of Mr Warrtore's experiment, from which Dr Priestley had been able to draw no conclusions, but had considered it merely as a curious fact. Without knowing any thing of Mr Watt's ideas, as far as appears to us, he made a number of ingenious experiments, which led him to conclude, that it was highly probable that water was a composition of air. The air which he employed seems not to have been pure; so that besides the water he procured a quantity of nitrous acid. He however acted like an able and candid philosopher; he went as far as his experiments would permit him, and he went no farther. In one point he continued to differ from Mr Watt after his theory was made public. Mr Watt supposed that water consisted of dephlogisticated air (oxygenous gas) and phlogiston (hydrogenous gas according to him), deprived of part of their latent heat; whereas Mr Cavendish thought there was no such thing as elementary heat. We must further add, that it was Mr Cavendish who taught Dr Priestley to turn to a proper account the experiment of Mr Warrtore; and therefore, that it was in fact from Mr Cavendish's experiments ultimately that Mr Watt was enabled to establish his theory.

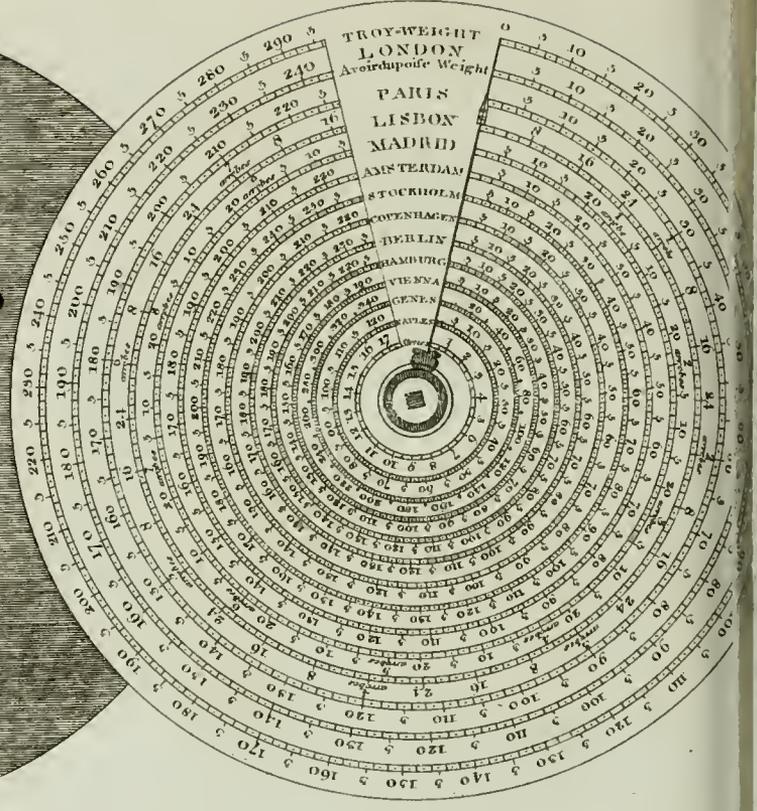

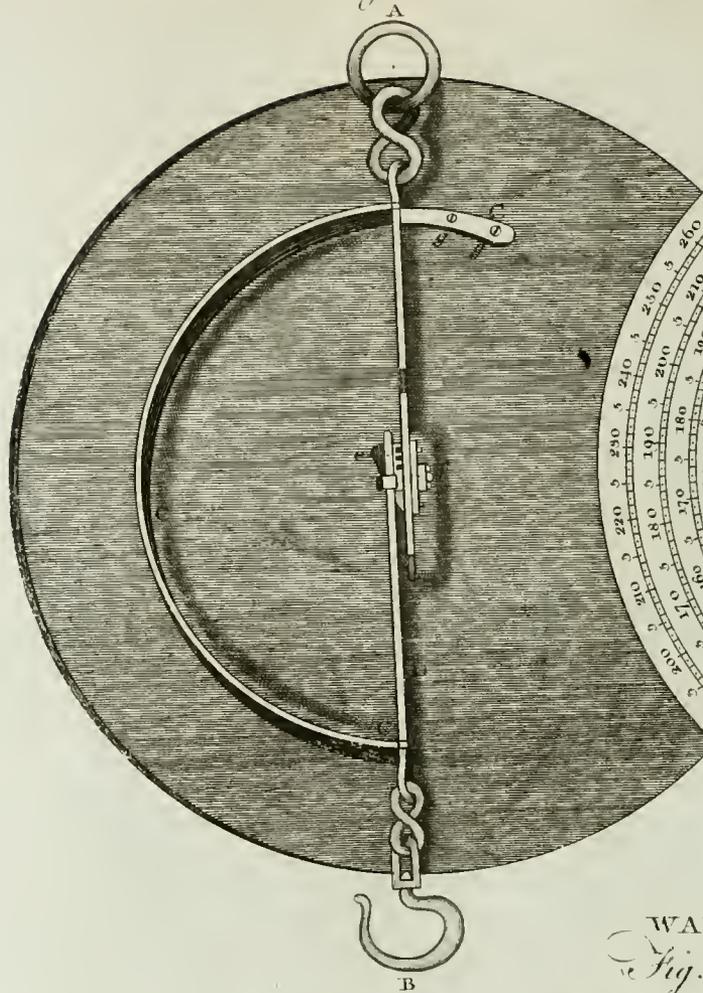

Of M vendi

The merit of Dr Priestley lies wholly in his being the instrument of promoting this discovery. He first published the experiment of Mr Warrtore; and when Mr Cavendish had informed him of the success he had met with in repeating that experiment, he began also to study the same subject. His discoveries were more useful to Mr Watt than to the author himself; for Mr Watt formed the theory which he had formerly been meditating; but Dr Priestley never came to a steady conclusion on the subject. We have read over carefully all his papers concerning the conversion of water

P Of Dr Priest

Fig. 2.

water into air, but cannot help saying, that we went along with the bewildered author weary and fatigued. His experiments are very often made at random, almost always founded on false principles, and seldom lead to any thing but to doubt and perplexity. M. Lavoisier sent him a copy of his ingenious paper on the composition of water; he repeated some of the experiments of that illustrious chemist, but he only involved himself in numberless difficulties. We are now no longer surpris'd at the singularity of Dr Priestley's opinions in religion; either at his incredulity in some things, or at his licentious sentiments in others. He that can doubt of the conclusive evidence which M. Lavoisier has given of the composition of water, must either have received less understanding than the bulk of mankind, or his mind must be warped with inextricable prejudices. With peculiar pleasure we mention Dr Black on this occasion. That gentleman, no less conspicuous for his candour and modesty than for his ingenuity, had, along with all other chemists of the time, believed the doctrine of phlogiston, and taught it in his public lectures; but, upon examining the Lavoisierian system, he was convinced of its truth, and had the honesty to confess it, though he was thus obliged to acknowledge to his students, that he had for many years been teaching errors. This acknowledgment does much honour to Dr Black, and proves that he is well entitled to the high character which he has so long held.

The merit of M. Lavoisier was great upon the present occasion. From England indeed he received the theory and the first experiments on the composition of water; but he was the first person who demonstrated the theory, and put it beyond doubt. His knowledge of the distinction between carbone and hydrogenic, as well as the perfect accuracy with which his experiments were made, enabled him to prove, with as much certainty as physical science generally admits, that water is composed of vital and inflammable air. We will now give some account of the proofs of this fact; and, as we have never seen them stated with more clearness and precision than by M. Lavoisier himself in his Elements of Chemistry, we shall take our account of them from him.

Proofs of the Composition of Water.

Exper. 1. Take a glass tube from 8 to 12 lines diameter, and place it across the furnace EFCD, with a gentle inclination from E to F (A). The higher extremity of the tube is then luted to the glass retort A, containing a known quantity of distilled water. To the lower extremity F is luted the worm SS, the lower end of which is fixed in the neck of the bottle H, which bottle has the bent tube KK fixed to a second opening. This bent tube is intended to carry off any elastic fluids which may escape into the bottle H. A fire is then lighted in the furnace EFCD, sufficient to keep the tube EF red hot, but not to melt it. The water in the retort A is kept boiling by a fire in the furnace VVXX. The water is gradually changed into steam by the heat of the two furnaces. It passes through the glass tube EF into the worm SS, where it is condensed, and then drops into the

bottle H. When the whole water is evaporated, and all the communicating vessels are emptied into the bottle H, it is found to contain exactly the same quantity which was put into the retort. This experiment therefore is a simple distillation.

Water.

Exper. 2. Every thing being disposed as in the last experiment, let 28 grains of pure charcoal, broken into small parts, and which has been exposed to a red heat in a close vessel, be introduced into the tube EF. The experiment is then performed in the same manner as the former. The water is evaporated, and a portion of it is again condensed in the worm SS, and then falls into the bottle H; but at the same time a considerable quantity of an elastic fluid escapes through the tube KK, which is received in vessels. When the water is entirely evaporated, and the tube examined, the 28 grains of charcoal have wholly disappeared.

When the water in the bottle H is examined, it is found to have lost 85.7 grains of its weight; and when the elastic fluid which passed off by the tube KK is weighed, it is found to weigh 113.7 grains, which is exactly the weight which the water has lost, added to the 28 grains of charcoal which had disappeared. The elastic fluid, on examination, is discovered to be of two kinds; namely, 144 cubical inches of carbonic acid gas weighing 100 grains, and 380 cubical inches of a very light gas weighing only 13.7 grains. Now 100 grains of carbonic acid gas consist of 72 grains of oxygene, combined with 28 grains of carbone. It is therefore evident, that the 28 grains of charcoal must have acquired 72 grains of oxygene from the water. It is also evident, that 85.7 grains of water are composed of 72 grains of oxygene, combined with 13.7 grains of a gas capable of being burned.

Exper. 3. Every thing being put in the same order as in the two former experiments, with this difference, that instead of the 28 grains of charcoal, 274 grains of soft iron, in thin plates rolled up spirally, are introduced into the tube EF. The tube is kept red hot while the water is evaporating from the retort. After the water has been distilled, it is found to have lost 100 grains. The gas or elastic fluid weighs 15 grains, and the iron has gained 85 grains additional weight, which put together make up 100 grains, the weight which the water has lost. The iron has all the qualities which it would have received by being burned in oxygene gas. It is a true oxyd (or calx) of iron. We have the same result as in the last experiment, and have therefore another proof for concluding, that 100 grains of water consist of 85 grains of oxygene, and 15 of the base of inflammable gas (B).

We have now exhibited two sufficient proofs, that water is composed of oxygene and hydrogenic; but as the composition of water is so interesting and important a subject, M. Lavoisier was not satisfied with these proofs alone. He justly concluded, that if water be a compound of two substances, it ought to follow, that by reuniting these two substances, water would be produced. He accordingly proved the truth of this conclusion by the following experiment.

15
Proof of
the composition
of
water by
synthesis

5 K

Exper.

(A) The tube EF should be made of glass which can bear a strong heat without melting. It should also be coated over with a lute composed of clay and powdered stone-ware; and to prevent it from bending during the experiment, it must be supported about the middle by an iron bar.

(B) This elementary substance Mr Lavoisier has denominated *hydrogenic*, which signifies "the generative principle of water;" from *υδωρ* "water," and *γενωμαι* "I produce." When this substance is combined with caloric, it is called *hydrogenous gas*. It is the lightest substance yet known, being $\frac{1}{16}$ th of the weight of an equal bulk of atmospheric air. It is very combustible, for it has so great an attraction for oxygene, that it attracts it from caloric; so that its inflammable property is merely its power of decomposing oxygenous gas, for it will not burn by itself. When drawn into the lungs, it produces instant death. See AEROLOGY.

Water. *Exper. 4.* He took a large crystal balloon A, fig. 2. containing about 30 pints, and having a large mouth; round which was cemented the plate of copper BC, pierced with four holes, through which four tubes pass. The first tube Hh is intended to exhaust the balloon of its air, by adapting it to an air pump. The second tube gg communicates with a reservoir of oxygenous gas placed at MM. The third tube d D is connected with a reservoir of hydrogenous gas at NN. The fourth tube contains a metallic wire GL, having a knob at its lower extremity L, from which an electric spark is passed to s, in order to set fire to the hydrogenous gas. The metallic wire is moveable in the tube, that the knob L may be either turned towards s, or away from it, as there is occasion. We must also add, that the three tubes Hh, gg, d D are furnished with stop-cocks.

It is necessary that the oxygenous gas, before being put into the reservoir, should be completely purified from carbonic acid. This may be done by keeping it for a long time in contact with a solution of caustic potash. The hydrogenous gas ought to be purified in the same manner. The quantity employed ought to be double the bulk of the oxygenous gas. It is best procured from water by means of iron, as was described in Experiment Third.

Great care must also be taken to deprive the oxygenous and hydrogenous gas of every particle of water. For this purpose they are made to pass in their way to the balloon A, through salts which have a strong attraction for water; as the acetite of potash (a compound of vinegar and vegetable alkali), or the muriate or nitrate of lime (the muriatic or nitric acid combined with lime). These salts are disposed in the tubes MM and NN of one inch diameter, and are reduced only to a coarse powder, that they may not unite into lumps, and interrupt the passage of the gasses.

Every thing being thus prepared for the experiment, the balloon is exhausted of its air by the tube Hh, and is filled with oxygenous gas. The hydrogenous gas is also pressed in through the tube d D by a weight of one or two inches of water. As soon as the hydrogenous gas enters the balloon, it is set fire to by an electric spark. The combustion can be kept up as long as we please, by supplying the balloon with fresh quantities of these two gasses. As the combustion advances, a quantity of water is collected on the sides of the balloon, and trickles down in drops to the bottom of it. By knowing the weight of the gasses consumed, and the weight of the water produced, we shall find that they are precisely equal. M. Lavoisier and M. Meusnier found that it required 85 parts by weight of oxygenous gas and 15 parts of hydrogenous gas to produce 100 parts of water.

Thus we have complete proofs, both analytical and synthetic, that water is not a simple elementary substance, as it has been long supposed, but is compounded of two elements, oxygene and hydrogen. We must add, that M. Lavoisier used the most scrupulous accuracy in making the experiments which we have described; and that he is of opinion that the proportions given above cannot be $\frac{1}{100}$ from the real truth. Such then is the history and proof of the composition of water. We come next to consider what substances are chemically united or dissolved in it.

Analysis of the different Substances contained in Water.

SINCE it is made certain by observation and experiment, that water contains many different kinds of substances; and as its qualities, and consequently its uses, differ much according to the nature of the substances combined with it—the knowledge of an easy and accurate method of analysing waters is become a matter of the utmost importance. By such an analysis we shall be enabled to select the purest wa-

ter for the purposes of life, and to avoid water which might be improper and hurtful; or, when good water cannot be had, to separate those substances from it which render it impure. By the same important art we shall find it easy to distinguish those waters which are best adapted to the arts and manufactures; we shall also be able to compare different mineral waters, to explain the causes of their effects in medicine; and to imitate those by art which are most efficacious.

All natural waters are more or less impure; for water has so strong an attraction for different substances, that it imbibes part of them in every situation in which it is found, not only when it flows over beds of earth, but when it filters through strata of metals, and even when it is dissolved in the atmosphere. Water cannot be procured in a pure state without undergoing the process of distillation.

Before we proceed to state the methods by which the different substances found in water may be detected, it will be proper to point out to the reader such sensible qualities of particular waters as may enable him to institute the process by which the analysis ought to be conducted. In every course of experiments, that order ought to be followed which will lead with most ease and certainty to the end which is in view; but unless a man from general knowledge be able to conjecture with some degree of accuracy what are the results to be expected in particular cases, he cannot be able to determine what experiments he ought to make.

The general circumstances which are first to be attended to in the examination of waters, are their colour, smell, taste, specific gravity, temperature, and local situation.

1. The first thing to be attended to in water is its colour. Pure water is transparent like crystal. Muddiness or a brown colour is a certain proof that some extraneous substance is diffused through the water. A green colour indicates the presence of iron, and a blue that of copper. If upon agitation airy bubbles appear in the water, we are sure that it contains carbonic acid or fixed air. The water which is to be examined with respect to colour should be put into a deep glass, that we may look down into a considerable body of it; for we shall thus discover any muddiness much better than by viewing the water horizontally through the glass.

2. We are next to observe whether the water has any smell. If it be pure, it will have no smell; if it diffuse a subtle penetrating odour, we have reason to conclude that it contains carbonic acid; if the smell of putrid eggs or of the scourings of a gun arise from it, we infer that it is impregnated with hepar sulphuris, or sulphur combined with an alkali.

3. Pure water has no taste. Water containing carbonic acid has a mild sourish taste. If it have a bitter taste, it may contain sulphate of soda or Glauber's salt, nitre or the sulphate, nitrate or muriate of magnesia, or lime combined with the nitric or muriatic acid. If the water has a slight austerity of taste, we may expect that it contains lime or gypsum; if it be saltish, it contains common salt; if the taste be lixivious, alkali is present; if æruginous, there is copper; if ferruginous or inky, we have reason to suppose that it contains iron.

4. The specific gravity of water can enable us to discover so that it contains some extraneous matter, but does not point out what sort of matter it is. We are always sure that the lightest waters are the purest. The standard to be employed for comparing the specific gravity of water to be examined is distilled water.

5. Another circumstance to be considered is the temperature of the water, whether it be hot, cold, or tepid. We must determine whether the temperature be the same during the whole year, or whether it depends on the weather; whether

whether it freezes in winter; if hot, whether, when allowed to cool, it deposits any sediment, and loses its taste and smell.

6. The local situation of the water must also be taken into review. We must consider the soil through which it flows, and inquire whether there be mines or veins of metals near, or any kind of substance which water can dissolve. We must also inquire whether the water flows in equal quantity during the whole year, or increases with rain, and decreases with dry weather: whether it is stagnant or flowing; if it flows, whether it flows swiftly or slowly: whether it deposits any sediment; and if it does, of what sort it is, whether a salt, earth, metal, or metallic ochre: whether it petrifies bodies thrown into it: and whether there be any sulphur to be found near it in a sublimed state.

It is also proper to observe whether it be hard or soft; whether any animalcules live or vegetables grow in it; and whether it has any reputation for its effects in medicine.

Water may be divided into two great divisions, *fresh* and *salt water*.—Fresh water may be divided into *atmospheric*, *stagnant*, and *running*.

Salt water comprehends most of the seas on the globe, but especially those of the torrid and the greater part of the temperate zones. It contains common salt in great quantity, sulphate or muriate of magnesia, and sulphate of lime, besides a great quantity of putrid matter brought into it by the rivers, or produced by the decomposition of the numerous tribes of animals which live and die in it. See *SEA* and *SEA-Water*.

Atmospheric water comprehends rain and snow water. Rain is the water which is evaporated from the sea and land, dissolved in the air, and afterwards discharged on the earth; it ought therefore to resemble distilled water in purity; and it would certainly do so, if the atmosphere did not abound with vapours and exhalations capable of being combined with it. It contains a small quantity of sulphate of lime, together with a very small portion of nitrous acid. The rain that drops from the tops of houses is always mixed with foot. Some showers have contained a quantity of the pollen of flowers, which has given rise to the stories of showers of sulphur. The rain which falls at a distance from towns, or after a long tract of wet weather, is purest; for the atmosphere is then in some measure washed, if we may use the expression, from all heterogeneous substances.—Snow water is contaminated with the same substances as rain water. When newly melted, it is destitute both of common air and of fixed air, or the carbonic acid. It is probably from the want of these that snow water is injurious to health.

Stagnant water forms a lake; and when a great quantity of earth is diffused through it, it forms a marsh. The water of lakes is generally very pure and transparent; for as they are not subject to so much agitation as streams, the substances that happen to fall into them are not much diffused, but soon subside to the bottom. Some lakes are salt.—Marshes are much more impure. They are generally contaminated with the putrid matter produced by the decomposition of animals and vegetables, and are often of a yellowish or brownish colour.

Running water comprehends spring and river water.—Spring water is the rain water, which, after discharging itself upon the earth, and being imbibed by it, again issues out. As it runs below the surface through different substances, it carries along with it such as it can dissolve, and is therefore not so pure as rain water. It often contains salts, earths, or metals.—Rivers consist of a collection of springs, and generally partake of the soil through which they pass. Rivers which run through great towns are load-

ed with animal and vegetable substances. But those which run at a distance from towns are purer than most springs; because, as they run with more rapidity, and to a greater distance, a great part of their impurities are thus volatilized. If the soil be soft through which a river runs, it will be full of earth; but if hard and rocky, the water is very clear and pure.

Water is called *hard* when it does not dissolve soap, or ²⁹Hard wa-boil vegetables, or make an infusion of tea. It generally contains some acid combined with absorbent earth, for which it has less attraction than for the alkali of the soap. When soap is put into such water, its alkali is immediately attracted by the acid of the water, the soap is decomposed, and the oil of it swims on the surface of the water. Water is not reckoned hard if it contains less than 10 grains of extraneous substances in the pound weight.

If the acid with which the absorbent earth is united be ³⁰the carbonic, the water may be purified by boiling. But ³¹rected. in order to make it agreeable to the palate after the calcareous earth is deposited, it ought to be exposed in the open air in broad shallow vessels. It will thus recover a portion of the air which was expelled by the boiling. But if the earth be suspended by any other acid, the water can be corrected by the addition of some fixed alkali, which immediately joins itself to the acid, while the earth is deposited. A solution of potash, or of any other alkali, may be poured into the water till it cease to produce any turbid appearance, or till no more is precipitated. The water must then be decanted from the sediment, or filtered if necessary.

Having now mentioned the different kinds of waters, it ³²Two me- will be next proper to describe the most accurate methods ³³of analyzing them. These are two, by precipitation and evaporation. Precipitants are substances which, being thrown into any impure water, separate the impurities, and throw ³⁴them to the bottom of the vessel. Precipitation is the most expeditious method of examining waters; but it does not enable us to form so accurate an estimate as is often necessary of the precise quantity of extraneous substances contained in them.

The other method of analyzing water is by evaporation, ³⁵And by e- which consists in separating the water from the impurities, ³⁶evaporation. by converting the water into steam, and crystallizing the salts contained in it. Both these methods are often necessary to be employed, either of them separately being defective. As the precipitants indicate the proper method of conducting the evaporation, it will be proper, before we describe how to analyze water by evaporation, to describe particularly the effects produced on it by applying different precipitants.

Method of analyzing Water by Precipitation.

THE substances hitherto found in water are, common at- ³⁷Substances mospherical air, acids, alkalis, earths, sulphurs, and metals. ³⁸contained in water.

Acids, when disengaged, may be discovered by turnsol ³⁹in water. or syrup of violets; and when combined with any base, they ⁴⁰Tests for may be detected by the nitrate of silver, muriate of barytes, ⁴¹discovering and lime-water. Uncombined alkalis are ascertained by ⁴²them.

Brazil wood and turmeric; in combination with acids, they may be detected by spirit of wine. Earths are precipitated by the acid of sugar and the acetous acid. Sulphur is discovered by the mineral acids; and metals are precipitated by lime-water and tincture of galls.

Most waters contain common atmospheric air. Fixed ⁴³Method of air, now called *carbonic acid*, is also found in all waters in ⁴⁴analyzing analyzing quantity from ⁴⁵water con- $\frac{1}{500}$ th part of the bulk of the water to a ⁴⁶tant amount bulk equal to the water itself. That some species of air ⁴⁷is common are contained in water, is evident from the small bubbles which ⁴⁸and carbonic acid

Water. may be often seen to rise in it when poured into a glass. These bubbles are still more distinguishable in water placed under the exhausted receiver of an air-pump; for the weight of the atmosphere being removed, the water expands; and the air contained in its interstices is thus let loose, and rises to the surface. The air may also be separated from water by boiling, and may be easily collected by a proper apparatus. Experiments may then be made upon it to determine its species and quantity.

³⁶ **Tests for carbonic acid in water.** Carbonic acid is known to be contained in water by the following marks: The taste is somewhat pungent, accecent, cooling, and very agreeable. The smell is subtle and penetrating. When agitated, it emits a number of air-bubbles, which give it the appearance of briskness. These are the sensible appearances which aerated water exhibits; but there are tests which chemistry furnishes much more decisive.

From a pigment called *litmus* is obtained a tincture called the *tincture of turnsol*. The litmus is wrapped up in a clean linen cloth, and steeped in distilled water; the water soon assumes a blue or violet colour, and is then fit for use. The tincture enables the chemist to discover the smallest particle of disengaged acid; for a few drops of it poured into water containing an acid immediately communicates a red colour to the whole fluid.

There is a more convenient method of using the turnsol: The saturated tincture is boiled with a little starch, and then a piece of paper is dipped into it, so as to tinge it completely. Paper thus tinged, when dipped into water containing an acid, instantly receives a red colour. The tincture is, however, a more delicate and sensible test than the tinged paper; for water saturated with aerial acid does not make any change in the colour of the paper; yet one part of aerated water gives a distinct red to 50 parts of the tincture.

³⁷ **And of collecting it.** The method of collecting and ascertaining the elastic fluids contained in water was unknown till the present age. The easiest method is to fill a vessel terminating in a narrow neck with aerated water, then tie to the neck a bladder from which all the air has been carefully squeezed. Let the aerated water be boiled; the elastic fluid is then expelled, and ascends into the bladder, where it is collected. The bladder may then be removed from the vessel, and its mouth tied up.

There is another method, which is much more accurate, for determining the quantity contained in any quantity of water: Fill a bottle or retort with aerated water, and let a stopper be put into its mouth, with a hole in it. Let one end of a crooked tube be inserted into the hole of the stopper, so closely that no air may escape at the joining; and let the other end of the tube be bent upwards into an inverted vessel full of mercury. Fire is then applied to the bottle or retort, and continued till the water boil. The heat carries off the air which is conveyed through the crooked tube into the inverted vessel of mercury. If the water be kept boiling for a short time, the whole or greater part of the elastic fluid will be expelled, and its bulk is estimated by the bulk of mercury which it has displaced. But it must be remembered, that the elastic fluid above the mercury is in a state of greater dilatation than the external air, for it is not pressed by the whole weight of the atmosphere; but, as M. Saussure observes, it is only charged with that weight diminished by the column of mercury.

³³ **And separate it from common air.** When the aerial fluid is thus collected, if we wish to separate the carbonic acid from the common air, the process is easy: Let the aerial fluid be separated from the mercury, while the external air is carefully excluded; and let the vessel containing it be inverted into another vessel containing

lime-water. The lime will immediately absorb the carbonic acid, and form calcareous earth, while the atmospherical air is left behind. The calcareous earth may then be weighed; and the carbonic acid being afterwards expelled, the loss of weight will give the quantity of carbonic acid.

The only other acids hitherto found in water besides the carbonic, are the sulphuric and muriatic acids. The presence of the sulphuric acid is most accurately ascertained by the muriate of barytes, which is a compound of the muriatic acid with barytes or ponderous earth. Barytes has so strong an attraction for the sulphuric acid, that it separates it from all other acids, and forms with it a compound called *ponderous spar*, which is insoluble in water. As the carbonate of alkali, or an aerated alkali, may produce a muddiness and precipitation resembling the effects of the sulphuric acid, it is necessary to add to it a few drops of the nitric acid, which will dissolve any portion of barytes precipitated by the aerated alkali.

The muriatic acid may be easily discovered, by throwing it into the water impregnated with it a little nitrate of silver (a compound of the nitric acid with silver). If there be the smallest portion of muriatic acid, it instantly seizes the silver, and is precipitated along with it in the appearance of a white mucilage. As the muriatic acid constitutes about one-fourth of the muriate of silver, we may easily determine its quantity, by subtracting one-fourth from the weight of the precipitate. Along with the nitrate of silver a little nitric acid should be added, for the reason mentioned in the last experiment.

Alkalis are known to exist in water by the lixivious or saltish taste which they communicate, by their effervescence with acids, and by several precipitants.

There are three tests which may be employed for discovering the presence of alkalis. 1. Paper tinged blue by the tincture of turnsol, and made red by distilled vinegar, recovers its blue colour when dipped into water containing an alkali. 2. The watery tincture of Brazil wood also serves to discover alkalis. It may either be used in the state of tincture, or a piece of paper may be tinged with it after being boiled with a little starch. In both cases it receives a blue colour from the alkali. One grain of soda dissolved in 4295 grains of water changes the colour of the tinged paper to a blue, which, though delicate, may be easily distinguished. 3. Watery tincture of turmeric is changed to a brown colour by alkalis. Paper tinged with this tincture boiled with starch is also affected in the same way. A single grain of soda dissolved in 859 grains of distilled water will obscure the yellow colour of the tinged paper, and turn it into a brownish hue.

The tincture of Brazil wood is remarkable for its sensibility in discovering the presence of an alkali. The tincture of turmeric is much slower in its decision; but this circumstance enables us, with some degree of accuracy, to estimate the quantity of alkali contained. The turmeric, too, answers best when there is occasion to examine an alkaline water by candle-light, as the change of colour which it produces is easily distinguishable.—Besides these tests now mentioned, any of the infusions of vegetables which are most easily affected by alkalis may be used with success, such as flowers of mallows and syrup of violets; but they are not on all occasions so decisive.

After being assured of the presence of an alkali, we must next determine what alkali it is. The alkalis most commonly found in water are the mineral and volatile, the vegetable seldom occurring. The mineral alkali is combined with the carbonic, sulphuric, or muriatic acid; the volatile is probably communicated by putrid animal or vegetable substances; and the vegetable is united with the sulphuric

or muriatic acid, but more frequently with the nitric acid. Bergman says, that mercury, dissolved in the nitric acid without heat, enables us to distinguish these alkalis. When a little of this solution is thrown into water, if a yellowish white substance is precipitated, we may conclude that a caustic vegetable alkali is present; if the precipitate be white, there is vegetable alkali saturated with the carbonic acid. If the precipitate be first yellow, and afterwards become white, mineral alkali is present; and if it be of a greyish black, we know that volatile alkali is present.

The species of alkali may be more easily ascertained, by pouring into the water a little sulphuric acid, or, what Morveau recommends as answering the purpose better, a little distilled vinegar, which with potash forms a deliquescent salt, and with soda a foliated crystallizable salt.

The earths which are molly found in waters are lime and magnesia. If any other earth has been discovered, it has been by so few chemists, and in such small portions, that it has been little attended to (c). Lime and magnesia are always united with the carbonic or some of the fossil acids. The carbonic acid is easily expelled by boiling the water, and the earth falls to the bottom, and may then be easily examined by applying sulphuric acid. If the earth be calcareous, with sulphuric acid it forms gypsum; if it be magnesia, Epsom salt is produced; and if it be clay, the product is alum.

Scarcely any water is entirely free from lime; even the purest water, after standing 24 hours, deposits some saccharated lime. The acid of sugar is one of the most sensible tests for discovering it. A small quantity of distilled water, in which there is dissolved a single grain of pure lime, will become muddy if the smallest quantity of the acid of sugar be thrown in. The presence of calcareous earth may also be discovered by employing the acetite of lead. It precipitates the earth in the form of a white powder. But as sulphuric acid also precipitates the acetite of lead, to make the experiment accurately, it is necessary to add a little distilled vinegar to the precipitate, and if it consist of calcareous earth, it will be immediately dissolved; but if it be a sulphate of lime, the vinegar will have no effect upon it.—When lime or magnesia is dissolved in any of the mineral acids, it may be detected by adding a little carbonate of potash. The nature of the earth may be afterwards easily determined.

Of the inflammable bodies, perhaps none has been found dissolved in water except sulphur. Sulphur is combined either with an alkali or with hydrogen, forming a sulphuret of hydrogen. Sulphuric or hepatic waters are easily known by the following marks: 1. A fetid smell, which is felt in approaching the spring. 2. The taste is strong, somewhat sweet, not unlike that of putrid eggs, but more disagreeable. 3. When a piece of silver is put into it, it becomes tarnished. 4. But the nicest test is a mark made on paper with the tartarite of bismuth or acetite of lead, which becomes black when exposed to the vapour of the hepatic water.

When we wish to discover the quantity of sulphur which is dissolved in an alkali, it may be precipitated by the sulphuric or muriatic acid, but much more plentifully by the nitric acid. To render the experiment successful, it is necessary that the mixture should be heated. When the nitric acid is dropped in, the sulphureous smell is instantly dissipated, the water grows turbid, and a white subtile powder slowly subsides. When dried, it is found to be genuine sul-

phur. When the water contains a fixed alkali, the acid has no effect in decomposing the sulphureous water till the alkali be saturated; but after the alkali is saturated, the hepatic air is then driven off by the acid, and the sulphur falls down.

Sulphureous water may easily be formed artificially: A quantity of hepar sulphuris, consisting of equal parts of sulphur and potash, is to be put into a vessel which communicates by a crooked tube with an inverted glass filled with water. Sulphuric acid is then poured into the vessel containing hepar sulphuris, a few drops at a time. The vessel containing the acid must communicate with the vessel containing the hepar sulphuris by a tube, that while the acid may be poured in at pleasure, the elastic gas which issues from the action of the acid on the hepar sulphuris may not be dissipated, but may pass into the inverted glass. This gas, if a candle be applied, will burn, and a residuum of sulphur of a whitish colour remains. The water in the inverted vessel must be frequently agitated, that the gas may be absorbed.

The metals hitherto found dissolved in waters are two, iron and copper. The former occurs often, the latter rarely. Iron is united with the carbonic or sulphuric acid, and may generally be detected by a greenish or yellowish colour, by its inky taste, by an ochre which it deposits, by tincture of galls, and by the Prussian alkali. Only the two last of these methods require any description. Spirit of wine saturated with powdered galls precipitates iron slowly; the precipitate is purple when the quantity of iron is small; but when the quantity is large, it is black. In some cases indeed iron may be present in water without giving a dark colour to the galls. This is owing to a superfluity of acid. But if a sufficient quantity of alkali be added to saturate the acid, the black colour will then appear.—The Prussian alkali is prepared from four parts of Prussian blue, boiled with one part of alkali in a sufficient quantity of water. The clear liquor must then be saturated with an acid, and filtered, that it may be freed from the small portion of Prussian blue which is separated. A single drop of this alkali dropped into water containing the sulphate of iron immediately forms a Prussian blue. In making experiments with this alkali, it is proper to add a little muriatic acid.

The quantity of iron contained in water may be ascertained with considerable accuracy, by the colour communicated by the tincture of galls: for if the tincture be poured into distilled water, then small pieces of iron may be added, till the liquor has acquired the colour of the chalybeate water; and then we may conclude, that the quantity of iron contained in the chalybeate water is equal to the artificial mixture, if the colour be the same. There is also another way of estimating the quantity of iron. When precipitated, let the residuum be washed in pure water, then dried and weighed. Pour upon it one of the mineral acids, and digest them together, and after pouring it off, wash what remains undissolved; then dry and weigh it again, and from the diminution of weight collect that of the iron. In this experiment the acid employed ought not to be very strong nor great in quantity, nor ought the digestion to be continued long; for if the residuum should contain any selenite which is soluble by acids, the selenite might seize upon a considerable portion of the acid, and consequently the experiment be inaccurate.

Copper is sometimes united in water with the sulphuric acid. It is discovered by the blue colour which it imparts

(c) A small quantity of siliceous earth was found by Bergman in an acidulous spring, as also by Dr Black in the Geyser spring in Iceland. Clay may also be often found in waters; but it is probably only dissolved, not chemically dissolved.

Water. to the water, by an æruginous taste, and by the ochre which it deposits. It may also be detected by throwing into the water a piece of polished iron; the copper will be precipitated upon the iron.

Method of analyzing Water by Evaporation.

50 General circumstances to be attended to. **HAVING** now described the methods of detecting the various substances contained in water by precipitation, we come next to describe how they are discovered by evaporation.

The vessels employed in evaporating the water ought to be broad, for fluids evaporate more quickly in proportion to the extent of the surface. If earthen vessels can be found of so close a texture as not to absorb any saline matter, they may be safely employed. Iron and copper vessels are improper, because they are liable to be corroded. The most convenient are thin glass vessels, which may without danger be exposed to a strong heat. The capacity of the vessels depends on the quantity of water which is necessary for the several experiments. The quantity of water may be small if it contain a large proportion of extraneous matter. The evaporation should be slow and gentle. The vessel employed ought to have a cover to keep out dust; but must have a hole several inches in diameter, that the vapours may issue out. The hole should not be opened till the vapour be so much condensed as to issue with such force as to keep the dust from falling in.

51 Order in which substances usually appear while water is evaporating. Some substances require more water to dissolve them than others. As the quantity of water is diminished by evaporation, they appear therefore in an order corresponding to their different degrees of solubility; those which are least soluble appearing first. The following is the order in which they are discovered: First carbonate of lime and carbonate of iron, then gypsum, then the sulphate of potash, then the sulphate of iron, then the nitrate of potash, and next in order the sulphate of copper; afterwards the muriate of potash, then soda, then the muriate of soda, then the sulphate of magnesia, and lastly the deliquescent salts. Aerated magnesia, or carbonate of magnesia, is not separated all at once, but continues to fall during the whole process. This order is often altered by the superabundance of any particular substance.

52 How the residuum should be treated. The different substances may be separated as they successively appear; but it is better to continue the evaporation to dryness. The residuum should be carefully collected and well dried. It is then put into a bottle, and alcohol poured on till it rise an inch above it. The bottle should then be closed and shaken. After standing for a few hours, the liquor may be filtered. What passes through the filter is preserved for a future analysis, and what remains behind has eight times its weight of cold distilled water poured upon it; the mixture is then shaken, allowed to stand for some time, and again filtered. What was dissolved by the water is preserved for future examination, and the residuum is then boiled for a quarter of an hour in somewhat more than four or five hundred times its weight of distilled water, and afterwards filtered.

53 When it shows a brown colour, should be exposed to the air. Being now purified by alcohol, cold water and hot water, the residuum is no longer soluble in alcohol or water. If it show a brown colour, this is a mark that iron is contained in it. To ascertain this point, it may be exposed for

some weeks in an open vessel to the rays of the sun, care being taken to moisten it from time to time. By the exposure to the air, the iron will imbibe oxygene, and is then no longer soluble in vinegar. The residuum may then be weighed; a quantity of acetous acid or distilled vinegar is then to be poured on it, and the mixture to be digested. By the digestion the acid will dissolve the carbonate of lime and magnesia, if there be any in the residuum. What the acid has not dissolved may be washed, dried, and weighed, and by its loss of weight it may easily be determined what the acid has taken up.

The matter dissolved by the acetous acid is then to be evaporated to dryness. It may be determined whether it contains calcareous earth or magnesia by this circumstance; if it consist of calcareous earth, it continues dry in a moist air; but if it contain magnesia, it is deliquescent. The same point may also be ascertained by the sulphuric acid. This acid added to calcareous earth, forms gypsum, or the sulphate of lime; but when added to magnesia, it dissolves it, forming the sulphate of magnesia or Epsom salt; or if the residuum contain both lime and magnesia, there will be produced both sulphate of lime and sulphate of magnesia. The precise quantity of the simple substances contained in each may be known by weighing the compound, and remembering that 100 parts of the sulphate of lime contain about 32 of pure lime, 46 of sulphuric acid, and 22 of water (D); and 100 parts of the sulphate of magnesia contain 19 of pure magnesia, 33 of sulphuric acid, and 48 of water (E).

That matter which was not dissolved by the acetous acid is either iron or silica. The iron is soluble by muriatic acid or by an alkali. The portion which resists the action of the muriatic acid is siliceous earth, which may be farther examined by the blow-pipe; for siliceous earth, when added to soda in a state of fusion, combines with it with a violent effervescence, and is thus changed into glass.

Having now shown how to examine the residue which was insoluble in alcohol and water, it will next be proper to describe how to analyze the solutions obtained by alcohol, cold water, and hot water.

1. The solution obtained by alcohol contains lime and magnesia, combined with the muriatic acid or with the nitric acid. To enable us to discover the nature and quantity of the ingredients, we evaporate them to dryness, and then pour sulphuric acid on the residue; the sulphuric immediately displaces the other acids, and unites with the base. If the base be lime, it forms a sulphate of lime; if it be magnesia, it produces the sulphate of magnesia.

2. The solution obtained by cold water must be examined by evaporation. The evaporation ought to be gentle, that the crystals may assume regular forms. The crystals, as they successively appear, are then to be placed on bibulous paper and dried; but not so much as to expel any of the water of crystallization. The species of the salt thus formed may be distinguished by the taste and shape of the crystals. But that they may be distinguished with accuracy, we shall mention other methods: The solution obtained by cold water may contain alkalis, neutral salts, salts united with earths, salts united with metals, and neutral salts combined with earths or metals.

The alkalis can easily be discovered by the methods

(D) The proportions given above are Bergman's; but Dr Kirwan estimates them differently. According to him, 100 parts of the sulphate of lime contain 32 of earth, 29,44 of acid, and 38,56 of water. When well dried, it loses about 24 of water, and therefore contains 42 of earth, 39 of acid, and 19 of water.

(E) According to Dr Kirwan, 100 grains of the sulphate of magnesia perfectly dry contain 45,67 of sulphuric acid, 36,54 of pure earth, and 17,83 of water. In crystals they contain 23,75 of acid, 19 of earth, and 57,25 of water.

mentioned above, but the neutral or compound salts will occasion more difficulty. We must first determine what the acid is, and with what base it is united. The sulphuric acid is detected by the muriate of barytes, as described above. The nitrous acid, when present, is expelled by the sulphuric acid, and may be easily distinguished by its smell and red fumes. It will be made still more evident by exposing its fumes to a paper moistened with ammonia or volatile alkali. The muriatic acid is easily detected by exposing the fumes of it to a paper moistened with water. This acid may also be discovered by the nitrate of silver.

It is more difficult to discover the bases of the neutral salts which are always alkalis. We formerly described the method of detecting them in water when disengaged, but we have now to separate them from an acid. Potash may be separated by barytes, soda is expelled by potash, and ammonia is expelled either by potash or soda.

We have mentioned already the method of discovering and distinguishing the earths and metals dissolved in water; but there is one compound which is extremely difficult to separate, viz. soda from common salt. The best method for effecting this is the process of M. Giaonetti: "It consists (says M. Fourcroy) in washing the mixed salt with distilled vinegar. The acid dissolves the mild soda; the mixture is dried, and washed afresh with spirit of wine, which is charged with the terra foliata mineralis, without touching the marine salt; the spirituous solution is evaporated to dryness, and the residuum calcined; the vinegar is decomposed and burned; we have then nothing but the mineral alkali, whose quantity is exactly found."

3. The solution obtained by boiling water contains only selenite or gypsum. This may be separated in crystals by evaporation to dryness, or it may be decomposed by an alkali.

We have now said every thing that is necessary respecting the two modes of analyzing water by precipitation and evaporation; but as a difficulty may occur to the unexperienced chemist respecting the order in which he ought to proceed in making his experiments, we shall lay before our readers the method recommended by M. Fourcroy.

He first examines the sensible properties of the water, the taste, colour, weight, &c. and then pours upon four pounds of water the same weight of lime-water. If no precipitate falls in 24 hours, he concludes that the water contains no disengaged carbonic acid, nor mild fixed alkali, nor earthy salts with base of aluminous earth or magnesia, nor metallic salts. If a precipitate be instantly formed, he proceeds to filter the liquid, and to examine the chemical qualities of the precipitate. If it has no taste, if it is insoluble in water, if it effervesces with acids, and if it forms with sulphuric acid an insipid salt almost insoluble in water, he concludes that it is chalk, and that the lime-water attracted only the aerial acid dissolved in the water. On the contrary, if the precipitate be not copious, if it collects slowly, if it excites no effervescence, if with the sulphuric acid it forms a bitter salt, it is magnesia; but if with the same acid it forms a sweetish astringent salt, it is aluminous earth or clay. Sometimes it may be a compound of both.

Being now examined by lime-water, he pours upon it other four pounds of the same water, a gros or two (℞) of volatile caustic alkali, or he passes it through some alkaline gas disengaged by means of heat. When the water is saturated, he leaves it in a close vessel for 24 hours; then a precipitate be formed, as it must contain salts, with

iron, magnesia, or aluminous earth for its base, he investigates the nature of it. It must be observed, that the alkaline gas is not to be depended upon alone, but may be used as an auxiliary.

M. Fourcroy next pours into a certain quantity of the water under examination a portion of caustic mineral alkali dissolved. He continues to pour it in till no farther mudiness is produced, as it decomposes the salts with a base of aluminous earth, or a base of lime. If the precipitate resembles in form, colour, and quantity, that which is yielded by lime-water, it may be presumed that the water contains no calcareous earth; but if it be more weighty, copious, and has formed more quickly than the precipitate formed by the lime-water, then it contains lime mixed with magnesia or aluminous earth. If the precipitate contain any iron, it is easily detected by its colour and taste.

These observations of M. Fourcroy will be of great use to the young chemist, in pointing out the order which he may follow with facility and advantage in the analysis of waters; and after he has formed his opinion concerning the ingredients contained in the water, he may examine the truth of it, by applying the particular tests which have already been described.

In the account which we have given of the method of analyzing waters, the chemical reader will observe, that we have chiefly followed Bergman. We have done so, because we reckon him the best writer on the subject, and because we have been more anxious to study truth and utility than novelty. We ardently wish that some able chemist would exhibit an accurate and easy mode of analyzing earths, which every farmer could practise without a deep knowledge of chemistry. Farmers would then be enabled to apply the manures proper to particular soils, in which they would be much assisted by Dr Kirwan's valuable Treatise on Manures.

Under the title of *MINERAL WATERS*, we have given an analysis of the most remarkable waters in Europe. (See also SPA, SELTZER, PYRMONT, and the names of other celebrated waters). Those who wish for more information concerning the mode of analyzing water, may consult Bergman's Chemical Essays, Fourcroy's Lectures on Chemistry, and the different books referred to by these authors.

Holy WATER, which is made use of in the church of Rome, as also by the Greeks, and by the other Christians of the East of all denominations, is water with a mixture of salt, blessed by a priest according to a set form of benediction. It is used in the blessing of persons, things, and places; and is likewise considered as a ceremony to excite pious thoughts in the minds of the faithful.

The priest, in blessing it, first, in the name of God, commands the devils not to hurt the persons who shall be sprinkled with it, nor to abuse the things, nor disquiet the places, which shall likewise be so sprinkled. He then prays that health, safety, and the favour of heaven, may be enjoyed by such persons, and by those who shall use such things, or dwell in such places. Vestments, vessels, and other such things that are set apart for divine service, are sprinkled with it. It is sometimes sprinkled on cattle, with an intention to free or preserve them from diabolical enchantments; and in some ritual books there are prayers to be said on such occasions, by which the safety of such animals, as being a temporal blessing to the possessors, is begged of God, whose providential care is extended to all his creatures. The hope which Catholics entertain of obtaining such good effects from the devout use of holy water, is grounded

Water. grounded on the promise made to believers by Christ (St Mark xvi. 17.), and on the general efficacy of the prayers of the church; the petition of which prayers God is often pleased to grant; though sometimes, in his Providence, he sees it not expedient to do so. That such effects have been produced by holy water in a remarkable manner, has been asserted by many authors of no small weight; as, namely, by St Epiphanius, Haer. 30th; St Hierom, in the Life of St Hilarion; Theodoret *Hist. Eccl.* lib. v. cap. 21.; Palladius, *Hist. Laus.*; Bede, lib. v. cap. 4.

As a ceremony (says the Catholic), water brings to our remembrance our baptism; in which, by water, we were cleansed from original sin. It also puts us in mind of that purity of conscience which we ought to endeavour always to have, but especially when we are going to worship our God. The salt, which is put into the water to preserve it from corrupting, is also a figure of divine grace, which preserves our souls from the corruption of sin; and is likewise an emblem of that wisdom and discretion which ought to season every action that a Christian does, and every word that he says. It is wont to be blessed and sprinkled in churches on Sundays, in the beginning of the solemn office. It is kept in vessels at the doors of the same churches, that it may be taken by the faithful as they enter in. It is also often kept in private houses and chambers (A).

Putrid WATER, is that which has acquired an offensive smell and taste by the putrefaction of animal or vegetable substances contained in it. It is in the highest degree pernicious to the human frame, and capable of bringing on mortal diseases even by its smell. It is not always from the apparent muddiness of waters that we can judge of their disposition to putrefy; some which are seemingly very pure being more apt to become putrid than others which appear much more mixed with heterogeneous matters. Under the article ANIMALCULE, n^o 33, is mentioned a species of insects which have the property of making water stink to an incredible degree, though their bulk in proportion to the fluid which surrounds them is less than that of one to a million. Other substances no doubt there are which have the same property; and hence almost all water which is confined from the air is apt to become offensive, even though kept in glass or stone-ware vessels. Indeed it is a common observation, that water keeps much longer sweet in glass-vessels, or in those of earthen or stone-ware, than in those of wood, where it is exceedingly apt to putrefy. Hence, as ships can only be supplied with water kept in wooden casks, sailors are extremely liable to those diseases which arise from putrid water; and the discovery of a method by which water could easily be prevented from becoming putrid at sea would be exceedingly valuable. This may indeed be done by quicklime; for when water is impregnated with it, all putrescent matters are either totally destroyed, or altered in such a manner as never to be capable of undergoing the putrefactive fermentation again. But a continued use of lime-water could not fail of being pernicious, and it is therefore necessary to throw down the lime; after which the water will have all the purity necessary for preserving it free from putrefaction. This can only be done by means of fixed air; and mere exposure in broad shallow vessels to the atmosphere would do it without any thing else, only taking care to break the crust which formed upon it. Two methods, however, have been thought of for doing this with more expedition. The one, invented by Dr Allston, is, by throwing into the wa-

ter impregnated with lime a quantity of magnesia. The lime attracts fixed air more powerfully than magnesia; in consequence of which the latter parts with it to the lime; and thus becoming insoluble, falls along with the caustic magnesia to the bottom, and thus leaves the water perfectly pure. Another method is that of Mr Henry, who proposes to throw down the lime by means of an effervescing mixture of oil of vitriol and chalk put down to the bottom of the water-cask. His apparatus for this purpose is as simple as it can well be made, though it is hardly probable that sailors will give themselves the trouble of using it; and Dr Allston's scheme would seem better calculated for them, were it not for the expence of the magnesia; which indeed is the only objection made to it by Mr Henry. Putrid water may be restored and made potable by a process of the same kind.

Of late it has been discovered that charcoal possesses many unexpected properties, and, among others, that of preserving water from corruption, and of purifying it after it has been corrupted. Mr Lowitz, whose experiments on charcoal have been published in Crell's Chemical Journal, has turned his attention to this subject in a memoir read to the Economical Society of Petersburg. He found that the effect of charcoal was rendered much more speedy by using along with it some sulphuric acid. One ounce and a half of charcoal in powder, and 24 drops of concentrated sulphuric acid (oil of vitriol), are sufficient to purify three pints and a half of corrupted water, and do not communicate to it any sensible acidity. This small quantity of acid renders it unnecessary to use more than a third part of the charcoal powder which would otherwise be wanted; and the less of that powder is employed, the less is the quantity of water lost by the operation, which, in sea-voyages, is an object worthy of consideration. In proportion to the quantity of acid made use of, the quantity of charcoal may be diminished or augmented. All acids produce nearly the same effects: neutral salts also, particularly nitre and sea-salt, may be used, but sulphuric acid is preferable to any of these; water which is purified by means of this acid and charcoal will keep a longer time than that which is purified by charcoal alone. When we mean to purify any given quantity of corrupted water, we should begin by adding to it as much powder of charcoal as is necessary to deprive it entirely of its bad smell. To ascertain whether that quantity of powdered charcoal was sufficient to effect the clarification of the said water, a small quantity of it may be passed through a linen bag, two or three inches long; if the water, thus filtrated, still has a turbid appearance, a fresh quantity of powdered charcoal must be added, till it is become perfectly clear: the whole of the water may then be passed through a filtering bag, the size of which should be proportioned to the quantity of water. If sulphuric acid, or any other, can be procured, a small quantity of it should be added to the water, before the charcoal powder.

The cleaning of the casks in which water is to be kept in sea-voyages should never be neglected: they should be well washed with hot water and sand, or with any other substance capable of removing the mucilaginous particles, and afterwards a quantity of charcoal-dust should be employed, which will entirely deprive them of the mufty or putrid smell they may have contracted.—The charcoal used for purifying water should be well burnt, and afterwards beat into a fine powder.

Sea-

(A) This article was furnished by an eminent divine of the church of Rome, to whom we are indebted for greater favours.

Sea-WATER. See *SEA-WATER.*

WATER-Carts, carriages constructed for the purpose of watering the roads for several miles round London; a precaution absolutely necessary near the metropolis, where, from such a vast daily influx of carriages and horses, the dust would otherwise become quite insufferable in hot dry weather. Pumps are placed at proper distances to supply these carts.

WATER-Ordeal. See *ORDEAL.*

WATER, among jewellers, is properly the colour or lustre of diamonds and pearls. The term, though less properly, is sometimes used for the hue or colour of other stones.

WATER-Bellows. See *Machines for blowing Air into Furnaces.*

WATER-Colours, in painting, are such colours as are only diluted and mixed up with gum-water, in contradistinction to oil colours. See *COLOUR-Making.*

WATER-Gang, a channel cut to drain a place by carrying off a stream of water.

WATER-Hen. See *PARRA.*

WATER-Line of a Ship, certain horizontal lines supposed to be drawn about the outside of a ship's bottom, close to the surface of the water in which she floats. They are accordingly higher or lower upon the bottom, in proportion to the depth of the column of water required to float her.

WATER-Lodged, the state of a ship when, by receiving a great quantity of water into the hold, by leaking, &c. she has become heavy and inactive upon the sea, so as to yield without resistance to the efforts of every wave rushing over her decks. As, in this dangerous situation, the centre of gravity is no longer fixed, but fluctuating from place to place, the stability of the ship is utterly lost: she is therefore almost totally deprived of the use of her sails, which would operate to overset her, or press the head under water. Hence there is no resource for the crew, except to free her by the pumps, or to abandon her by the boats as soon as possible.

WATER-Sail, a small sail spread occasionally under the lower studding-sail, or driver-boom, in a fair wind and smooth sea.

WATER-Ouzel. See *TURDUS.*

WATER-Spout, an extraordinary meteor consisting of a large mass of water collected into a sort of column, and moved with rapidity along the surface of the sea.

The best account of the water-spout which we have met with is in the *Phil. Trans. Abridged*, vol. viii. as observed by Mr Joseph Harris, May 21. 1732, about sunset, lat. 32° 00' N. long. 9° E. from Cape Florida.

“When first we saw the spout (says he), it was whole and entire, and much of the shape and proportion of a speaking trumpet; the small end being downwards, and reaching to the sea, and the big end terminated in a black thick cloud. The spout itself was very black, and the more so the higher up. It seemed to be exactly perpendicular to the horizon, and its sides perfectly smooth, without the least ruggedness. Where it fell the spray of the sea rose to a considerable height, which made somewhat the appearance of a great smoke. From the first time we saw it it continued whole about a minute, and till it was quite dissipated about three minutes. It began to waste from below, and so gradually up, while the upper part remained entire, without any visible alteration, till at last it ended in the black cloud above: upon which there seemed to fall a very heavy rain in that neighbourhood.—There was but little wind, and the sky elsewhere was very serene.”

Water-spouts have by some been supposed to be merely electrical in their origin: particularly by the late Uccellaria,

who supported his opinion by some experiments. But if we attend to the successive phenomena necessary to constitute a complete water-spout through their various stages, we shall be convinced, that recourse must be had to some other principle in order to obtain a complete solution.

Dr Franklin, in his *Physical and Meteorological Observations*, supposes a water-spout and a whirlwind to proceed from the same cause; their only difference being, that the latter passes over the land, and the former over the water. This opinion is corroborated by M. de la Prynne, in the *Philosophical Transactions*, where he describes two spouts observed at different times in Yorkshire, whose appearances in the air were exactly like those of the spouts at sea, and their effects the same as those of real whirlwinds.

A fluid moving from all points horizontally towards a centre, must at that centre either mount or descend. If a hole be opened in the middle of the bottom of a tub filled with water, the water will flow from all sides to the centre, and there descend in a whirl: but air flowing on or near the surface of land or water, from all sides towards a centre, must at that centre ascend; because the land or water will hinder its descent.

The Doctor, in proceeding to explain his conceptions, begs to be allowed two or three positions, as a foundation for his hypothesis. 1. That the lower region of air is often more heated, and so more rarefied, than the upper, and by consequence specifically lighter. The coldness of the upper region is manifested by the hail, which sometimes falls from it in warm weather. 2. That heated air may be very moist, and yet the moisture so equally diffused and rarefied as not to be visible till colder air mixes with it; at which time it condenses and becomes visible. Thus our breath, although invisible in summer, becomes visible in winter.

These circumstances being granted, he presupposes a tract of land or sea, of about 60 miles in extent, unsheltered by clouds and unrefreshed by the wind, during a summer's day, or perhaps for several days without intermission, till it becomes violently heated, together with the lower region of the air in contact with it; so that the latter becomes specifically lighter than the superincumbent higher region of the atmosphere, wherein the clouds are usually floated: he supposes also that the air surrounding this tract has not been so much heated during those days, and therefore remains heavier. The consequence of this, he conceives, should be, that the heated lighter air should ascend, and the heavier descend; and as this rising cannot operate throughout the whole tract at once, because that would leave too extensive a vacuum, the rising will begin precisely in that column which happens to be lightest or most rarefied; and the warm air will flow horizontally from all parts of this column, where the several currents meeting, and joining to rise, a whirl is naturally formed, in the same manner as a whirl is formed in a tub of water, by the descending fluid receding from all sides of the tub towards the hole in the centre.

And as the several currents arrive at this central rising column, with a considerable degree of horizontal motion, they cannot suddenly change it to a vertical motion; therefore as they gradually, in approaching the whirl, decline from right to curve or circular lines, so, having joined the whirl, they ascend by a spiral motion: in the same manner as the water descends spirally through the hole in the tub before mentioned.

Lastly, as the lower air nearest the surface is more rarefied by the heat of the sun, it is more impressed by the current of the surrounding cold and heavy air which is to assume its place, and consequently its motion towards the whirl is swifter, and so the force of the lower air is

Water

whirl strongest, and the centrifugal force of its particles greatest. Hence the vacuum which incloses the axis of the whirl should be greatest near the earth or sea, and diminish gradually as it approaches the region of the clouds, till it ends in a point.

This circle is of various diameters, sometimes very large.

If the vacuum passes over water, the water may rise in a body or column therein to the height of about 32 feet. This whirl of air may be as invisible as the air itself, though reaching in reality from the water to the region of cool air, in which our low summer thunder-clouds commonly float; but it will soon become visible at its extremities. The agitation of the water under the whirling of the circle, and the swelling and rising of the water in the commencement of the vacuum, renders it visible below. It is perceived above by the warm air being brought up to the cooler region, where its moisture begins to be condensed by the cold into thick vapour, and is then first discovered at the highest part, which being now cooled condenses what rises behind it, and this latter acts in the same manner on the succeeding body; where, by the contact of the vapours, the cold operates faster in a right line downwards, than the vapours themselves can climb in a spiral line upwards: they climb however; and as by continual addition they grow denser, and by consequence increase their centrifugal force, and being risen above the concentrating currents that compose the whirl, they fly off, and form a cloud.

It seems easy to conceive, how, by this successive condensation from above, the spout appears to drop or descend from the cloud, although the materials of which it is composed are all the while ascending. The condensation of the moisture contained in so great a quantity of warm air as may be supposed to rise in a short time in this prodigiously rapid whirl, is perhaps sufficient to form a great extent of cloud; and the friction of the whirling air on the sides of the column may detach great quantities of its water, disperse them into drops, and carry them up in the spiral whirl mixed with the air. The heavier drops may indeed fly off, and fall into a shower about the spout; but much of it will be broken into vapour, and yet remain visible.

As the whirl weakens, the tube may apparently separate in the middle; the column of water subsiding, the superior condensed part drawing up to the cloud. The tube or whirl of air may nevertheless remain entire, the middle only becoming invisible, as not containing any visible matter.

Dr Lindfay, however, in several letters published in the Gentleman's Magazine, has controverted this theory of Dr Franklin, and endeavoured to prove, that water-spouts and whirlwinds are distinct phenomena; and that the water which forms the water-spout, does not ascend from the sea, as Dr Franklin supposes, but descends from the atmosphere. Our limits do not permit us to insert his arguments here, but they may be seen in the Gentleman's Magazine, volume li. p. 559, 615; vol. liii. p. 1025; and vol. lv. p. 594. We cannot avoid observing, however, that he treats Dr Franklin with a degree of asperity to which he is by no means intitled, and that his arguments, even if conclusive, prove nothing more than that some water-spouts certainly

do descend; which Dr Franklin hardly ever ventured to deny. There are some very valuable dissertations on this subject by professor Wilcke of Upsal.

WATER-Works. See *Water-Works* (A).

WATER-Works for entertainment. See *HYDROSTATICS*, sect. 6.

WATERFORD, a city and sea-port of Ireland, in a county of the same name, with a bishop's see. It is the second place in the kingdom, and is a wealthy, populous city, enjoying many ample privileges. The streets are narrow, and the air is not very healthy; but it has an excellent harbour, seated as well for trade as any in the world, and ships of the greatest burden may ride at the quay. It stands on the river Sure, 8 miles north of St George's Channel, 6 south of Kilkenny, and 75 south by west of Dublin. W. Long. 6. 54. N. Lat. 52. 18.

WATERFORD, a county of Ireland, 46 miles in length, and 25 in breadth; bounded on the south by St George's Channel; on the west by Cork; on the north by the river Sure, which separates it from Tipperary and Kilkenny; and on the east by Waterford Haven, which parts it from Wexford. It contains 71 parishes, and sends 10 members to parliament. It is a fine country, very pleasant and rich, and the principal place is of the same name.

WATERING, in the manufactures, is to give a lustre to stuffs, &c. by wetting them lightly with gum-water, and then passing them through the press or calender whether hot or cold. The gum-water ought to be pure, thin, and clear, otherwise the folds of the stuff will all stick together: the operation must also be performed when the water is very hot, that it may penetrate.

WATERING Meadows. See *MEADOWS*.

WATERLAND (Dr Daniel), a learned English divine who distinguished himself greatly in theological controversies, was born in 1683 at Wasely in Lincolnshire, of which place his father was rector. He had his academical learning at Magdalen college, Cambridge, where he drew up a useful tract, which went through several editions, intitled, *Advice to a Young Student, with a Method of Study for the first four years*. In 1713 he became master of the college, was soon after appointed chaplain to George I. and in 1720 preached the first course of lectures founded by lady Meyer in defence of our Lord's divinity. He went through several promotions; and at the time of his death in 1740, was canon of Windsor, archdeacon of Middlesex, and vicar of Twickenham. Besides his controversial writings, he published two volumes of sermons.

WATLING-STREET. See *WAY*.

WATSON (Dr Robert), an elegant historian, was born at St Andrew's, in Scotland, about the year 1730. He was the son of an apothecary of that place, who was also a brewer. Having gone through the usual course of languages and philosophy at the school and university of his native place, and also entered on the study of divinity, a desire of being acquainted with a larger circle of literati, and of improving himself in every branch of knowledge, carried him, first to the university of Glasgow, and afterwards to that of Edinburgh. The period of theological studies

(A) For referring this article from the word **WATER** to the word **WORKS**, an apology is due to the Public; and the apology which we have to offer, we are persuaded, will be sustained. It is this: The gentleman who contributed the articles *RESISTANCE of Fluids* and *RIVER*, promised to furnish also the article *WATER-Works*; but sickness has hitherto prevented him from fulfilling that promise. We trust, however, that before our presses shall reach to the word **WORKS**, he may be able to fill up the sketch which he has long ago drawn of this very important subject. And such of our readers as can estimate the merit of his two articles, which we have just mentioned, will not blame the Editor for deviating a little from the alphabetical order, to give him a chance of furnishing a third article, to which these two are so closely related.

60n. Justice at the universities of Scotland is four years: but during that period, young men of ingenious minds find sufficient leisure to carry on and advance the pursuits of general knowledge. Mr Watson pursued his studies with ardour. Few men ever studied more constantly. It was a rule with him to study eight hours every day; and this law he observed during the whole course of his life. An acquaintance with the polite writers of England, after the union of the two kingdoms, became general in Scotland; and in Watson's younger years, an emulation began to prevail of writing pure and elegant English. Mr Watson applied himself with great industry to the principles of philosophical or universal grammar; and by a combination of these, with the authority of the best English writers, formed a course of lectures on style or language. He proceeded to the study of rhetoric or eloquence; the principles of which he endeavoured to trace to the nature of the human mind. He delivered a course of lectures in Edinburgh on these subjects; and met with the countenance, approbation, and friendship of Lord Kames, Mr Hume, with other men of genius and learning.

At this time he had become a preacher; and a vacancy having happened in one of the churches of St Andrew's, he offered himself a candidate for that living, but was disappointed. Mr Henry Rymer, who then taught logic in St Salvador's College, was in a very infirm state of health, and entertained thoughts of retiring from the cares and emoluments of his office, to live upon his small salary or stipend. Mr Watson understanding this, purchased, for not a great sum of money, what, in familiar phraseology, may be called the good-will of Mr Rymer's place; and, with the consent of the other masters of St Salvador's, was appointed professor of logic. He obtained also a patent from the crown, constituting him professor of rhetoric and belles lettres. The study of logic, in St Andrew's, as in most other places, was at this time confined to syllogisms, modes, and figures. Mr Watson, whose mind had been opened by conversation, and by reading the writings of the wits that had begun to flourish in the Scotch capital, prepared and read to his students a course of metaphysics and logics on the most enlightened plan; in which he analyzed the powers of the mind, and entered deeply into the nature of the different species of evidence of truth or knowledge. By his history of Philip II. Dr Watson attained in his lifetime a considerable degree of celebrity; and his history of Philip III. published after his death, has added to his fame. Of this last performance, however, he has only completed the four first books; the two last were written by the editor of his manuscript, at the desire of the guardians of his children.

On the death of principal Tulideph, Dr Watson, through the care of Kinnoull, was appointed his successor; in which station he lived only a few years. He married a lady of singular beauty and virtue, daughter to Mr Shaw, professor of divinity in St Mary's college, St Andrew's. By this lady he had five daughters, who survived him.

WAITS (Dr Isaac), a learned and eminent dissenting minister, was born at Southampton in 1674, of parents eminent for piety, and considerable sufferers for conscience-sake. In 1690 he was sent up to London for academical education under the tuition of the Rev. Mr Thomas Rowe; and in 1696 was himself engaged as tutor to the son of Sir John Hartopp, bart. at Stoke Newington. He began to preach in 1698, and met with general acceptance; and after officiating for three years as an assistant to the Rev. Dr Isaac Chauncy, he succeeded in his pastoral charge in 1702, and continued to preside over that church as long as he lived. Though his whole income did not amount to an hundred a-

year, he allotted one third of it to the poor. He died in 1748. His numerous works have rendered his name famous among people of every denomination, both in this and other countries, and they have been translated into a variety of languages. His *Lyric Poems*, his *Psalms and Hymns*, and his *divine Songs for Children*, are a sufficient proof of his poetical talents, and have had an amazing number of editions. His logic and philosophy have been much admired. He also wrote works upon a variety of other subjects, and printed several volumes of his sermons. He was admired for the mildness and benevolence of his disposition and the sweetness of his manners. After his death, his works were collected, and published in six volumes quarto.

WAVE, in philosophy, a cavity in the surface of water, or other fluids, with an elevation aside thereof.

The waves of the sea are of two kinds, natural and accidental. The natural waves are those which are exactly proportioned in size to the strength of the wind, whose blowing gives origin to them. The accidental waves are those occasioned by the wind's reacting upon itself by repercussion from hills and mountains, or high shores, and by the washing of the waves themselves; otherwise of the natural kind, against rocks and shoals: all these cases give the waves an elevation, which they can never have in their natural state. For the height of the waves, see SEA.

Stilling WAVES by means of Oil. See SEA.

WAVED, in heraldry, is said of a bordure, or any ordinary or charge, in a coat of arms, having its outlines indented in manner of the rising and falling of waves: it is used to denote, that the first of the family in whose arms it stands, acquired its honours by sea service.

WAVING, in the sea-language, is the making signs to a vessel to come near or keep off.

WAX, or *Bees Wax*, in natural history, a firm and solid substance, moderately heavy, and of a fine yellow colour, formed by the bees from the pollen of flowers. See APIS.

The best sort is that of a lively yellow colour, and an agreeable smell, somewhat like that of honey: when new, it is toughish, yet easy to break; but by age it becomes harder and more brittle, loses its fine colour, and in a great measure its smell.

It appears that wax and the pollen have for their basis a fat oil, which passes to the state of resin by its combination with oxygen. If the nitric or muriatic acid be digested upon fixed oil for several months, it passes to a state resembling wax. Wax, by repeated distillations, affords an oil which possesses all the properties of volatile oils. It is reduced into water and carbonic acid by combustion. The colouring matter of wax is insoluble in water and in alcohol.

Fixed alkalis dissolve wax, and render it soluble in water. It is this saponaceous solution which forms the punic wax. It may be used as the basis of several colours; and may be made into an excellent pail for washing the hands. Ammoniac likewise dissolves it; and as this solvent is evaporable, it ought to be preferred when it is proposed to use the wax as a varnish.

From the common yellow wax, by bleaching, is formed white-wax, sometimes called, very improperly, *virgin-wax*. The greater the surface is in proportion to the quantity, the sooner and more perfectly this operation is performed. The usual way is to melt the wax in hot water; when melted, they press it through a strainer of tolerable fine linen, and pour it into round and very shallow moulds. When hardened by cooling, it is taken out and exposed to the sun and air, sprinkling it now and then with water, and often tuning it: by this means it soon becomes white.

W
Way.

The best sort is of a clear and almost transparent whiteness, dry, hard, brittle, and of an agreeable smell, like that of the yellow wax, but much weaker.

The common yellow wax is of very great use both in medicine and in many of the arts and manufactures. It has been sometimes given internally in dysenteries and erosions of the intestines; but its great use is in the making of ointments and plasters, and the greater part of those of the shops owe their consistence to it. The white wax is also an ingredient in some of the cerates and ointments of the shops; and is used in making candles, and in many of the nicer arts and manufactures where wax is required.

Sealing-Wax, or *Spanish-Wax*, is a composition of gum lac, melted and prepared with resins, and coloured with some suitable pigment.

There are two kinds of sealing-wax in use; the one hard, intended for sealing letters, and other such purposes; the other soft, designed for receiving the impressions of seals of office to charters patents, and such written instruments. The best hard red sealing-wax is made by mixing two parts of shell lac, well powdered, and resin and vermilion, powdered, of each one part, and melting this combined powder over a gentle fire; and when the ingredients seem thoroughly incorporated, working the wax into sticks. Seed-lac may be substituted for the shell-lac; and instead of resin, boiled Venice turpentine may be used. A coarser, hard, red sealing-wax, may be made, by mixing two parts of resin, and of shell-lac, or vermilion and red-lead, mixed in the proportion of one part of the vermilion to two of the red lead, of each one part; and proceeding as in the former preparation. For a cheaper kind, the vermilion may be omitted, and the shell-lac also, for very coarse uses. Wax of other colours is made by substituting other colouring matters for vermilion, as verdit for blue, ivory black for black wax. For uncoloured, soft sealing-wax, take of bees wax, one pound; of turpentine, three ounces; and of olive-oil, one ounce; place them in a proper vessel over the fire, and let them boil for some time; and the wax will be then fit to be formed into rolls or cakes for use. For red, black, green, blue, yellow, and purple soft sealing-wax, add to the preceding composition an ounce or more of any ingredients directed above for colouring the hard sealing-wax, and stir the mass till the colouring ingredients be incorporated with the wax.

Wax-Work, the representation of the faces, &c. of persons living or dead; made by applying plaster of Paris in a kind of paste, and thus forming a mould containing the exact representation of the features. Into this mould melted wax is poured, and thus a kind of masks are formed; which being painted and set with glass eyes, and the figures dressed in their proper habits, they bear such a resemblance that it is difficult to distinguish between the copy and the original.

WAY, a passage or road.

The Roman ways are divided into consular, prætorian, military, and public; and of these we have four remarkable ones in England: the first, Watling-street, or Watheling-street, leading from Dover to London, Dunstable, Ponceiler, Atterton, and the Severn, extending as far as Anglesea in Wales. The second, called *Hik-nild* or *Ikenild-street*, stretches from Southampton over the river Isis at Newbridge; thence by Camden and Litchfield; then passes the Derwent near Derby, and ends at Timmouth. The third, called *Fosse-way*, because in some places it was never perfected, but lies as a large ditch, leads from Cornwall through Devonshire, by Tethbury, near Stow in the Wolds; and beside Coventry to Leicester, Newark, and so to Lincoln. The fourth,

called *Erming* or *Erminige-street*, extends from St David's, in Wales, to Southampton.

Way-Covert, *Ging*, *Hatch*. See *COVERT Way*, *GANG*, &c.

Way of a Ship, is sometimes the same as her rake, or run forward or backward: but this term is most commonly understood of her sailing.

Way-Leaves, in the coal business. See *COALERY*, n^o 3.

Right of Ways, in law. This may be grounded on a special permission; as when the owner of the land grants to another a liberty of passing over his grounds, to go to church, to market, or the like: in which case the gift or grant is particular, and confined to the grantee alone; it dies with the person; and if the grantee leaves the country, he cannot assign over his right to any other; nor can he justify taking another person in his company. A way may be also by prescription; as if all the owners and occupiers of such a farm have immemorially used to cross another's ground; for this immemorial usage supposes an original grant, whereby a right of way thus appurtenant to land may clearly be created. A right of way may also arise by act and operation of law; for if a man grants me a piece of ground in the middle of his field, he at the same time tacitly and impliedly gives me a way to come at it; and I may cross his land for that purpose without trespass. For when the law doth give any thing to one, it giveth impliedly whatsoever is necessary for enjoying the same. By the law of the twelve tables at Rome, where a man had the right of way over another's land, and the road was out of repair, he who had the right of way might go over any part of the land he pleased: which was the established rule in public as well as private ways. And the law of England, in both cases, seems to correspond with the Roman.

WAYFARING TREE. See *VIBURNUM*.

WAYWODE, is properly a title given the governors of the chief places in the dominions of the czar or Muscovy. The palatines, or governors of provinces in Poland, also bear the quality of *waywodes*, or *waywods*. The Poles likewise call the princes of Wallachia and Moldavia *waywodes*; as esteeming them no other than on the part of governors; pretending that Wallachia and Moldavia are provinces of Poland. Everywhere else these are called *hopodars*. Du Cange says, that the name *waywode* is used in Dalmatia, Croatia, and Hungary, for a general of an army: and Leunclavius, in his *Pandects of Turkey*, tells us, it usually signifies *captain or commander*.

WEANING, putting a child away from the breast, and bringing it to use common food.

WEAR, or **WEER**, a great flank or dam in a river, fitted for the taking of fish, or for conveying the stream to a mill. New wears are not to be made, or others altered, to the nuisance of the public, under a certain penalty. See *RIVER*.

WEARING, or **VEERING**, in seamanship. See *SEAMANSHIP*, Vol. XVII. p. 219.

WEASEL, in zoology. See *MUSTELA*.

WEATHER denotes the state of the atmosphere with regard to heat and cold, wind, rain, and other meteors.

The phenomena of the weather must have at all times attracted much of the attention of mankind, because their subsistence and their comfort in a great measure depended upon them. It was not till the seventeenth century, however, that any considerable progress was made in investigating the laws of meteorology. How desirous soever the ancients might have been to acquire an accurate knowledge of this science, their want of proper instruments entirely precluded them from cultivating it. By the discovery of the barometer and thermometer in the last century, and the invention of accurate electrometers and hygrometers in the present,

present, this defect is now pretty well supplied; and philosophers are enabled to make meteorological observations with ease and accuracy. Accordingly a very great number of such observations have been collected, which have been arranged and examined from time to time by ingenious men, and consequences deduced from them, on which several different theories of the weather have been built. But meteorology is a science so exceedingly difficult, that, notwithstanding the united exertions of some of the first philosophers of the age, the phenomena of the weather are still very far from being completely understood; nor can we expect to see the veil removed, till accurate tables of observations have been obtained from every part of the world, till the atmosphere has been more completely analysed, and the chemical changes which take place in it ascertained. From the meteorological facts, however, which are already known, we shall draw up the best account of the weather we can. We shall treat of the different phenomena in the following order—heat and cold, wind, rain, thunder, alterations in the gravity of the atmosphere.

I. Though there is a considerable difference in every part of the world between the temperature of the atmosphere in summer and in winter; though in the same season the temperature of almost every day, and even every hour, differs from that which precedes and follows it; though the heat varies continually in the most irregular and seemingly capricious manner—still there is a certain mean temperature in every climate, which the atmosphere has always a tendency to observe, and which it neither exceeds nor comes short of beyond a certain number of degrees. What this temperature is, may be known by taking the mean of tables of observations kept for a number of years; and our knowledge of it must be the more accurate the greater the number of observations is.

The mean annual temperature is greatest at the equator (or at least a degree or two on the north side of it), and it diminishes gradually towards the poles, where it is least. This diminution takes place in arithmetical progression, or, to speak more properly, the annual temperature of all the latitudes are arithmetical means between the mean annual temperature of the equator and the pole. This was first discovered by Mr Mayer; and by means of an equation which he founded on it, but rendered considerably plainer and simpler, Mr Kirwan has calculated the mean annual temperature of every degree of latitude between the equator and the pole. He proceeded on the following principle. Let the mean annual heat at the equator be m and at the pole $m-n$; put ϕ for any other latitude; the mean annual temperature of that latitude will be $m-n \times \sin. \phi^2$. If therefore the temperature of any two latitudes be known, the value of m and n may be found. Now the temperature of north lat. 40° has been found by the best observations to be $62,1^\circ$, and that of lat. 50° , $52,9^\circ$. The square of the sine of 40° is nearly $0,419$, and the square of the sine of 50° is nearly $0,586$. Therefore

$$m - 0,419n = 62,1 \text{ and}$$

$$m - 0,586n = 52,9 \text{ ; therefore}$$

$$62,1 + 0,419n = 52,9 + 0,586n, \text{ as each of}$$

them, from the two first equations, is equal to m . From this last equation the value of n is found to be 53 nearly; and m is nearly equal to 84 . The mean temperature of the equator therefore is 84° , and that of the pole 31° . To find the mean temperature for every other latitude, we have only to find 88 arithmetical means between 84 and 31 . In this manner Mr Kirwan calculated the following table.

Table of the Mean Annual Temperature of the Standard Ocean, in every Latitude.

Lat.	Temper.	Lat.	Temper.	Lat.	Temper.
90	31,	61	43,5	32	69,1
89	31,04	60	44,3	31	69,9
88	31,10	59	45,09	30	70,7
87	31,14	58	45,8	29	71,5
86	31,2	57	46,7	28	72,3
85	31,4	56	47,5	27	73,8
84	31,5	55	48,4	26	74,8
83	31,7	54	49,2	25	75,5
82	32,	53	50,2	24	76,4
81	32,2	52	51,1	23	77,9
80	32,6	51	52,4	22	79,5
79	32,9	50	52,9	21	80,2
78	33,2	49	53,8	20	81,8
77	33,7	48	54,7	19	83,3
76	34,1	47	55,6	18	84,9
75	34,5	46	56,4	17	86,4
74	35,	45	57,5	16	87,9
73	35,5	44	58,4	15	89,4
72	36,	43	59,4	14	90,8
71	36,6	42	60,3	13	91,3
70	37,2	41	61,2	12	91,7
69	37,8	40	62,	11	92,
68	38,4	39	63,	10	92,3
67	39,1	38	63,9	9	92,7
66	39,7	37	64,8	8	92,9
65	40,4	36	65,7	7	93,2
64	41,2	35	66,6	6	93,4
63	41,9	34	67,4	5	93,6
62	42,7	33	68,3	0	84,

This table, however, only answers for the temperature of the atmosphere of the ocean. It was calculated for that part of the Atlantic ocean which lies between the 80th degree of northern and the 45th of southern latitude, and extends westwards as far as the Gulf-stream, and to within a few leagues of the coast of America; and for all that part of the Pacific ocean reaching from lat. 45° north to lat. 40° south, from the 20th to the 275th degree of longitude east of London. This part of the ocean Mr Kirwan calls the *standard*; the rest of the ocean is subject to anomalies which will be afterwards mentioned.

Mr Kirwan has also calculated the mean monthly temperature of the standard ocean. The principles on which he went were these: The mean temperature of April seems to approach very nearly to the mean annual temperature; and as far as heat depends on the action of the solar rays, the mean heat of every month is as the mean altitude of the sun, or rather as the sine of the sun's altitude. The mean heat of April, therefore, and the sine of the sun's altitude being given, the mean heat of May is found in this manner: As the sine of the sun's mean altitude in April is to the mean heat of April, so is the sine of the sun's mean altitude in May to the mean heat of May. In the same manner the mean heats of June, July, and August, are found; but the rule would give the temperature of the succeeding months too low, because it does not take in the heat derived from the earth, which possesses a degree of heat nearly equal to the mean annual temperature. The real temperature of these

Weather: these months therefore must be looked upon as an arithmetical mean between the astronomical and terrestrial heats. Thus in latitude 51°, the astronomical heat of the month of September is 44.6, and the mean annual heat is 52.4; therefore the real heat of this month should be $\frac{44.6 + 52.4}{2}$

= 48.5. Mr Kirwan, however, after going through a tedious calculation, found the results to agree so ill with observations, that he drew up the following table partly from principles and partly by studying a variety of sea-journals.

TABLE of the Monthly Mean Temperature of the Standard from lat. 80° to lat. 10°.

Lat.	80°	79°	78°	77°	76°	75°	74°	73°	72°	71°	70°	69°	68°	67°	66°	65°	64°	63°	62°	61°	60°	59°	58°

From this table it appears, that January is the coldest month in every latitude, and that July is the warmest month in all latitudes above 48°. In lower latitudes August is generally warmest. The difference between the hottest and coldest months increases in proportion to the distance from the equator. Every habitable latitude enjoys a mean heat of 60 for at least two months; this heat seems necessary for the production of corn. Within ten degrees of the poles the temperatures differ very little, neither do they differ much within ten degrees of the equator; the temperature of different years differ very little near the equator, but they differ more and more as the latitudes approach the poles.

The temperature of the earth at the level of the sea is the same with that of the standard ocean; but this temperature gradually diminishes as we ascend above that level till, at a certain height, we arrive at the region of perpetual congelation. This region varies in height according to the latitude of the place; it is highest at the equator, and descends gradually nearer the earth as we approach the poles. It varies also according to the season, being highest in summer and lowest in winter. M. Bouguer found the cold on the top of Pinchinca, one of the Andes, to extend from seven to nine degrees below the freezing point every morning immediately before sun-rise. He concluded, therefore, that the mean height of the *term of congelation* (the place where it first freezes during some part of the day all the year round) between the tropics was 15,577 feet above the level of the sea; but in lat. 28° he placed it in summer at the height of 13,440 feet. Now, if we take the difference between the temperature of the equator and the freezing point, it is evident that it will bear the same proportion to the term of congelation at the equator that the difference between the mean temperature of any other degree of latitude and the freezing point bears to the term of congelation in that latitude. Thus the mean heat of the equator being 84, the difference between it and 32 is 52; the mean heat of lat. 28° is 72.3, the difference between which and 32 is 40.3: Then 52 : 15577 :: 40.3 : 12072. In this manner Mr Kirwan calculated the following table,

Mean height of the Term of Congelation.		Mean height of the Term of Congelation.	
LAT.	FEET.	LAT.	FEET.
0	15577	45	7658
5	15457	50	6260
10	15067	55	4912
15	14498	60	3684
20	13719	65	2516
25	13030	70	1557
30	11592	75	748
35	10664	80	120
40	9016		

If the elevation of a country above the level of the sea proceeds at a greater rate than six feet per mile, we must, according to Mr Kirwan *, for every 200 feet of elevation diminish the annual temperature of the standard in that latitude as follows. If the elevation be at the rate of

- 6 feet per mile $\frac{1}{3}$ of a degree
- 7 feet - $\frac{1}{4}$
- 13 feet - $\frac{1}{5}$
- 15 or upwards $\frac{1}{6}$

According to him † also, for every 50 miles distance from the standard ocean, the mean annual temperature in different latitudes is to be depressed or raised nearly at the following rate:

From lat. 70° to lat. 35° cooled $\frac{1}{2}$ of a degree
35 - - - $\frac{1}{4}$
30 - - - 0
25 warmed $\frac{1}{4}$
20 - - - $\frac{1}{2}$
10 - - - 1°

The cause of the heat of the atmosphere is evidently the sun's rays; this has been observed and acknowledged in all ages. The heat which they produce is less according as they fall more obliquely; hence the temperature constantly diminishes from the equator to the pole, because their obliquity constantly increases with the latitude. But if the heat depended on the solar rays alone, it would disappear in the

the polar regions during winter when the sun ceases to rise. This, however, is by no means the case; the mean temperature, even at the pole, is 31° ; and we find within the arctic circle as hot weather as under the equator. The reason of this is, that the sun's rays heat the earth considerably during summer: this heat it retains and gives out slowly during winter, and thus moderates the violence of the cold; and summer returns before the earth has time to be cooled down beyond a certain degree. This is the reason that the coldest weather does not take place at the winter solstice, but some time after when the temperature of the earth is lowest; and that the greatest heat takes place also some considerable time after the summer solstice, because then the temperature of the earth is highest. For pure air is not heated by the solar rays which pass through it, but acquires slowly the temperature of the earth with which it is in contact. This is the reason why the temperature decreases according to the elevation above the level of the sea (A).

3
And of the
difference
between
the temper-
ature on
land and
sea.

Since the atmosphere is heated by contact with the superficies of the earth, its temperature must depend upon the capacity of that superficies for receiving and transmitting heat. Now this capacity differs very much in land and water. Land, especially when dry, receives heat with great readiness, but transmits it through its own substance very slowly. Dr Hailes found, that in 1724, when the air and surface of the earth were both at 88° , a thermometer placed only two inches below the surface stood at 85° ; another 16 inches below the surface, at 70° ; and another 24 inches deep, at 68° . The two last-mentioned thermometers retained the same temperature till the end of the month, though the temperature of the air frequently varied, and then fell only to 63° or 61° . The earth, at about 80 or 90 feet below its surface, constantly retains the same temperature; and this is nearly equal to the mean annual heat of the country. Hence the mean annual temperature of any country may be found out pretty accurately, by examining the heat of deep wells or springs. Water, on the contrary, receives heat slowly, on account of its transparency; but what it does receive, is very quickly transfused through the whole mass.

Land is often heated and cooled to a much greater degree than sea is. Dr Raymond often found the earth in the neighbourhood of Marseilles heated to 170° , but he never found the sea above 77° : in winter the earth was often cooled down to 14° , but the sea never lower than 45° . The sea atmosphere, therefore, ought to preserve a much more uniform temperature than the land atmosphere; and we find this in fact to be the case. The cause of the greater equability of water than land is evident. In summer the surface of the sea is constantly cooled down by evaporation; and in winter, whenever the surface is cooled, it descends to the bottom from its increased gravity, and its place is supplied by warmer water. This process goes on continually, and the winter is over before the atmosphere has been able to cool down the water beyond a certain degree. It must be remembered also, that water has a greater capacity for heat than land has, and therefore is longer either in heating or cooling.

These observations will enable us to explain the difference which takes place between the annual temperature of the atmosphere above the ocean and that of places at some consider-

able distance from it. As the sea is never heated so highly as the land, the mean summer temperature at sea may be considered, all over the world, as lower than on land. During winter, when the power of the sun's rays in a great measure ceases, the sea gives out heat to the air much more readily than the earth: the mean winter temperature, therefore, at sea is higher than on land; and in cold countries the difference is so great, that it more than counterbalances the difference which takes place in summer; so that in high latitudes the mean annual temperature ought to be greater at sea than on land. Accordingly from lat. 70° to 35° , to find the temperature of a place, the standard temperature for the same latitude ought, according to Dr Kirwan, to be depressed $\frac{1}{4}$ of a degree for every 50 miles distance; for the cold which takes place in winter always increases in proportion to the distance from the standard. At a less distance than 50 miles the temperatures of land and sea are so blended together by sea and land winds, that there is little difference in the annual mean. In lower latitudes than 30° , the rays of the sun, even in winter, retain considerable power; the surface of the earth is never cooled very low, consequently the difference between the annual temperatures of the sea and land becomes less. As we approach nearer to the equator, the power of the solar rays during winter increases so that the mean winter temperature of the land atmosphere approaches nearer and nearer to that of the sea, till at last at the equator it equals it. After we pass lat. 30° , therefore, the mean annual land temperature gradually exceeds that of the sea more and more till at the equator it exceeds it a degree for every 50 miles distance.

Such then, in general, is the method of finding the mean annual temperature over the globe. There are, however, several exceptions to these general rules, which come now to be mentioned.

That part of the Pacific ocean which lies between north lat. 52° and 66° is no broader at its northern extremity than 42 miles, and at its southern extremity than 1300 miles: it is reasonable to suppose, therefore, that its temperature will be considerably influenced by the surrounding land, which consists of ranges of mountains covered, a great part of the year, with snow; and there are besides a great many high, and consequently cold, islands scattered through it. For these reasons Mr Kirwan concludes, that its temperature is at least 4 or 5 degrees below the standard. But we are not yet furnished with a sufficient number of observations to determine this with accuracy.

It is the general opinion, that the southern hemisphere, beyond the 40th degree of latitude, is considerably colder than the corresponding parts of the northern hemisphere. The cause of this we shall endeavour to assign in the article WIND.

Small seas surrounded with land, at least in temperate and cold climates, are generally warmer in summer and colder in winter than the standard ocean, because they are a good deal influenced by the temperature of the land. The Gulph of Botnia, for instance, is for the most part frozen in winter; but in summer it is sometimes heated to 70° , a degree of heat never to be found in the opposite part of the Atlantic*. The German sea is above three degrees colder in winter, and five degrees warmer in summer, than the Atlantic†. The Mediterranean Sea is, for the greater part of its extent, warmer both in summer and winter than

(A) It was some time ago the favourite opinion of philosophers, that the heat of the earth was derived from a mass of fire in its centre. But there does not seem any probability in the opinion, as the heat of the earth does not increase the deeper we go, but remains constant nearly at the mean heat of the place. In the mine of Joachimsthal in Bohemia, one of the deepest existing, Mr Monnet found the temperature at the depth of 1700 feet to be 50° . The temperature of the earth has even been found to diminish the deeper we go, though never lower than 36° .

the Atlantic, which therefore flows into it. The Black Sea is colder than the Mediterranean, and flows into it †.

The eastern parts of North America are much colder than the opposite coast of Europe, and fall short of the *standard* by about 10° or 12°, as appears from American Meteorological Tables. The causes of this remarkable difference are many. The highest part of North America lies between the 40th and 50th degree of north latitude, and the 100th and 110th degree of longitude west from London; for there the greatest rivers originate. The very height, therefore, makes this spot colder than it otherwise would be. It is covered with immense forests, and abounds with large swamps and morasses, which render it incapable of receiving any great degree of heat; so that the rigour of winter is much less tempered by the heat of the earth than in the old continent. To the east lie a number of very large lakes; and farther north, Hudson's Bay; about 50 miles on the south of which there is a range of mountains which prevent its receiving any heat from that quarter. This bay is bounded on the east by the mountainous country of Labrador and by a number of islands. Hence the coldness of the north-west winds and the lowness of the temperature. But as the cultivated parts of North America are now much warmer than formerly, there is reason to expect that the climate will become still milder when the country is better cleared of woods, though perhaps it will never equal the temperature of the old continent.

Islands are warmer than continents in the same degree of latitude; and countries lying to the windward of extensive mountains or forests are warmer than those lying to the leeward. Stones or sand have a less capacity for heat than earth has, which is always somewhat moist; they heat or cool, therefore, more rapidly and to a greater degree. Hence the violent heat of Arabia and Africa, and the intense cold of Terra del Fuego. Living vegetables alter their temperature very slowly, but their evaporation is great; and if they be tall and close, as in forests, they exclude the sun's rays from the earth, and shelter the winter snow from the wind and the sun. Woody countries, therefore, are much colder than those which are cultivated.

Thus we have endeavoured to ascertain the mean temperature of every climate, and to assign the causes by which that temperature is governed. Mr Kirwan, in his admirable Treatise on the Temperature of Different Latitudes, has done much to reduce this part of meteorology to regularity, and to subject it to calculation; and he has in some measure succeeded. To enable our readers to judge how far his rules agree with facts, we shall subjoin a table of the mean temperature of a variety of places drawn up from actual observations.

†† East. Trav. vol. II. p. 229.

†† Mem. Soci. 1771.

As to the daily variations of the temperature of the atmosphere, they are owing to a variety of causes; many of which are probably unknown. Some of them, however, are the following: 1. Wind. It is evident that winds blowing from cold countries must produce cold, and from hot countries heat; and that whatever has a tendency to produce such winds must be the cause of unusual cold or heat.— 2. Evaporation. Water always absorbs a quantity of heat when it assumes the state of vapour. Hence the coldness of marshy countries, and the cold which we often experience during and after violent rains. Hence also we may expect a cold winter after a rainy summer, because the unusual evaporation carries off the heat of the earth.— 3. Vapour, when condensed, gives out a quantity of heat; a country, therefore, may be heated by the condensation over it of vapour brought from a distance. Hence the thick fogs often felt before rain.— 4. Vapours, when they remain long over any country, may produce cold by obstructing the passage of the sun's rays to the earth. To this cause Dr Franklin ascribed the very severe winter which followed 1783; a year remarkable for the thick fog which overspread Europe and America.

Weather. America during several months.—5. When, from any of these causes, the winter has been severer than usual, prodigious quantities of ice may accumulate about the pole, which may contribute something perhaps towards lowering the temperature of several succeeding years.

15
Of WINDS. II. The winds evidently have a very great influence on the weather; the causes which produce them, therefore, ought to be examined with the greatest attention. Were we able to regulate their motions, we might, in a great measure, mould the climate of any country according to our pleasure; were we able to force them, it would be of the greatest importance to navigation and agriculture. In the torrid zone, where they are regular, the mean annual temperature remains almost always the same; their irregularity increases as we approach the pole, and in the same manner the difference between the mean annual temperature increases with the latitude.

Wind is produced chiefly by the action of the sun on the atmosphere; there are many other causes, however, and some perhaps of which we are yet ignorant. But we shall reserve this part of our subject, on account of its importance and extent, for a separate article.

16
Of RAIN. III. We come now to the most difficult part of our subject, the phenomena and causes of rain. It has been long known, that water is constantly rising from the whole surface of the globe, in the form of vapour, and mixing with the atmosphere. Evaporation has been ascribed to various causes; but the greater number of philosophers have for some time past acquiesced in the theory first advanced by Dr Halley, that it was produced by a real solution of water in air, just as sugar or salt is dissolved in water. This theory is supported by a great many very plausible arguments, which at the first view seem to establish its truth.—These arguments, however, are not all of them so conclusive as they appear. Thus it was thought, that because evaporation was promoted by heat, and retarded by cold, it bore an exact resemblance to the solution of salts in liquids: but it is now known that evaporation is not so much retarded by cold as was at first supposed; that in some circumstances it is even promoted by it; and that it does not depend so much upon the absolute degree of heat or cold, as upon the difference of temperature between the atmosphere and the evaporating surface: Besides, water evaporates much more rapidly in a vacuum than in the open air, which could not possibly be the case if evaporation were owing to the solution of water in air.

Evaporation, then, cannot be owing to solution of water in air; it is produced by the combination of a certain quantity of caloric with the particles of water, by which it is converted into an elastic fluid lighter than air, which therefore immediately ascends and mixes with the atmosphere. This was long ago shown by Dr Black to be the way in which steam or the vapour arising from boiling water is produced. The same principles were afterwards applied by Mr De Luc to spontaneous evaporation; and the proofs upon which this theory rests are quite convincing. But though evaporation is not produced by air, vapour would very soon condense and return to its former state by contact with colder bodies, unless it were attracted and supported by air.

17
Causes of evaporation. We are indebted to the experiments of Saussure and De Luc for much of our knowledge of the qualities of vapour. It is an elastic invisible fluid like common air, but lighter; being to common air, according to Saussure, as 10 to 14, or, according to Kirwan, as 10 to 12: it cannot pass beyond a certain maximum of density, otherwise the particles of water which compose it unite together, and form small, hollow, visible vesicles, called *vesicular vapour*; which is of the

same specific gravity with atmospherical air. It is of this vapour that clouds and fogs are composed. This maximum increases with the temperature; and at the heat of boiling water is so great, that steam can resist the whole pressure of the air, and exist in the atmosphere in any quantity. See METEOROLOGY, n^o 7—23.

Evaporation, at least in our climate, is about four times greater during the summer than the winter half-year: other things being equal, it is so much the more abundant the greater the difference is between the temperature of the air and of the evaporating surface; so much the less, the nearer they approach to the same temperature; and least of all when they actually arrive at it. Whenever the atmosphere is more than 15 degrees colder than the evaporating surface, little evaporation takes place at all. Evaporation is powerfully promoted by winds, especially cold winds blowing into warm countries, or warm winds blowing into cold countries*. Tracts of land covered with trees or vegetables emit more vapour than the same space covered with water. From the experiments of Mr Williams, the quantity appears to be one-third more †. But the method in which these experiments were made (the same objection lies against several of Dr Hailes's experiments, the original discoverer of the fact) prevented him from ascertaining exactly the quantity of vapour emitted by plants. He made the plants grow in a box well closed up from the air, measured the quantity of water with which he supplied them, and at the end of the experiment weighed the box and the plants themselves. By this means he knew pretty accurately the quantity of water which the plants had absorbed, and which had afterwards disappeared; and all this he concluded had been emitted by the plants in the state of vapour. But it is well known that plants have the power of decomposing water, of retaining the hydrogen, and throwing off the oxygen. A part of the water then was decomposed and changed into air; and the quantity of this ought to have been ascertained and subtracted. Still, however, the quantity of vapour emitted by vegetables is very great. Evaporation is promoted by heat, and is therefore much greater in the torrid zone than in our latitudes. There, too, the difference between the quantities in summer and winter is much less than in our climate, because the difference between the temperature of the two seasons is less. Animals also are continually throwing off vapour by insensible perspiration; the quantity of which is exceedingly different, according to the climate, season, and temperament, and cannot therefore be calculated exactly. According to Keil, a single man perspires 31 ounces of vapour in 24 hours, and consequently 707 pounds of water in a year. The quantity of vapour then which is emitted by animals alone must be very great.

From an experiment made by Dr Watson in England, during summer, when the earth had been burnt up by a month's drought without rain, it appears that 1600 gallons of water were evaporated from a single acre in 12 hours.—If we were to suppose that this represented the mean daily evaporation all over the globe, it would be easy to calculate the quantity of water annually evaporated from the whole of its surface. And if we consider the state of the earth when the experiment was made, the situation of England nearer the pole than the equator, and the evaporation constantly going on from animals and vegetables, which is not taken into account, we will surely not think the mean assumed too great. 1600 gallons in 12 hours is 3200 in 24 hours. Let us call it only 3000, which is equal to 693,000 cubic inches. An acre contains 272,640 square inches; so that the daily evaporation from every square inch will be about .11 of a cubic inch. This in a year will amount to somewhat more than 40 cubic inches for every square inch. From the

experiments of Mr Williams *, it appears, that in Bradford in New England the evaporation during 1772 amounted to 42,65 inches; but from the way that his experiments were conducted, the amount was probably too great. These experiments, however, serve to show, that our calculation is not perhaps very remote from the truth. 40 inches from every square inch on the superficies of the globe makes 107,942 cubic miles, equal to the water annually evaporated over the whole globe.

Were this prodigious mass of water all to subsist in the atmosphere at once, it would increase its mass by about a twelfth, and raise the barometer nearly three inches. But this never happens, no day passes without rain in some part of the earth; so that part of the evaporated water is constantly precipitated again. Indeed it would be impossible for the whole of the evaporated water to subsist in the atmosphere at once, at least in the state of vapour.

M. De Saussure has shown, that when the thermometer is at 66°, a cubic foot of air cannot contain more vapour than what is equivalent to 8 grains of water. If more than this be added, it will pass its maximum, be converted into vesicular vapour, and at last fall down in drops of rain. At the temperature of 32° a cubic foot of air can contain only 4 grains, and the quantity it can contain is increased .1109 of a grain by every additional degree of heat. Supposing then that the whole atmosphere was saturated with water, it would not amount to the hundredth part of the quantity of water evaporated annually.

The quantity of vapour existing in the atmosphere is indicated by the hygrometer. Water has the property of arriving at a state of equilibrium in hygroscopic substances: that is, supposing a certain quantity of water attached to a hygroscopic substance, if another hygroscopic substance be brought into contact with it containing less water, some of the water attached to the first substance will leave it, and attach itself to the other, till both contain the same proportion of water. Air is a hygroscopic substance, and so is every thing of which hygrometers are made. Now the hygrometer never points at extreme moisture while the air continues transparent, and consequently contains nothing but invisible vapour; the atmosphere therefore, while transparent, never contains the greatest possible quantity of vapour.

The higher regions of the atmosphere contain less vapour than the strata near the surface of the earth. This was observed both by M. De Saussure and M. De Luc, who mentions several striking proofs of it. See METEOROLOGY, no 10, &c.

At some height above the tops of mountains the atmosphere is probably still drier; for it was observed both by Saussure and De Luc, that on the tops of mountains the moisture of the air was rather less during the night than the day. And there can be little doubt that every stratum of air descends a little lower during the night than it was during the day, owing to the cooling and condensing of the stratum nearest the earth. Vapours, however, must ascend very high, for we see clouds forming far above the tops of the highest mountains.

Rain never begins to fall while the air is transparent: the invisible vapours first pass their maximum, and are changed into vesicular vapours; clouds are formed, and these clouds gradually dissolve in rain. Clouds, however, are not formed in all parts of the horizon at once; the formation begins in one particular spot, while the rest of the air remains clear as before: this cloud rapidly increases till it overpreads the whole horizon, and then the rain begins.

It is remarkable, that though the greatest quantity of va-

pours exist in the lower strata of the atmosphere, clouds never begin to form there, but always at some considerable height. It is remarkable, too, that the part of the atmosphere at which they form has not arrived at the point of extreme moisture, nor near that point even a moment before their formation. They are not formed then, because a greater quantity of vapour had got into the atmosphere than could remain there without passing its maximum. It is still more remarkable, that when clouds are formed, the temperature of the spot in which they are formed is not always lowered, though this may sometimes be the case. On the contrary, the heat of the clouds themselves is sometimes greater than that of the surrounding air. Neither then is the formation of clouds owing to the capacity of air for combining with moisture being lessened by cold: so far from that, we often see clouds, which had remained in the atmosphere during the heat of the day, disappear in the night, after the heat of the air was diminished.

The formation of clouds and rain, then, cannot be accounted for by a single principle with which we are acquainted. It is neither owing to the saturation of the atmosphere, nor the diminution of heat, nor the mixture of airs of different temperatures, as Dr Hutton supposes; for clouds are often formed without any wind at all either above or below them; and even if this mixture constantly took place, the precipitation, instead of accounting for rain, would be almost imperceptible.

It is a very remarkable fact, that evaporation often goes on for a month together in hot weather without any rain. This sometimes happens in this country; it happens every year in the torrid zone. Thus at Calcutta, during January 1785, it never rained at all*: the mean of the thermometer for the whole month was 66½ degrees; there was no high wind, and indeed during great part of the month little wind at all.

The quantity of water evaporated during such a drought must be very great; yet the moisture of the air, instead of being increased, is constantly diminishing, and at last disappears almost entirely. For the dew, which is at first copious, diminishes every night; and if Dr Watson's experiment formerly mentioned be attended to, it will not be objected that the quantity of evaporation is also very much diminished. Of the very dry state to which the atmosphere is reduced during long droughts, the violent thunder-storms with which they often conclude is a proof, and a very decisive one. Now what becomes of all this moisture? It is not accumulated in the atmosphere above the country from which it was evaporated, otherwise the whole atmosphere would in a much less period than a month be perfectly saturated with moisture. If it be carried up daily through the different strata of the atmosphere, and waded to other regions by superior currents of air, how is it possible to account for the different electrical state of the clouds situated between different strata, which often produces the most violent thunder-storms? Are not vapours conductors of the electric fluid; and would they not have daily restored the equilibrium of the whole atmosphere through which they passed? Had they traversed the atmosphere in this manner, there would have been no negative and positive clouds, and consequently no thunder-storms. They could not have remained in the lower strata of the atmosphere, and been daily carried off by winds to other countries; for there are often no winds at all during several days to perform this office: nor in that case would the dews diminish, nor could their presence fail to be indicated by the hygrometer.

It is impossible for us to account for this remarkable fact upon any principle with which we are acquainted. The water can neither remain in the atmosphere, nor pass thro-

Weather.

And it is sometimes a new form of the atmosphere.

Weather. it in the state of vapour. It must therefore assume some other form; but what that form is, or how it assumes it, we know not.

26
The conversion into oxygen and hydrogen improbable.

It will immediately occur to every body, that vapour is decomposed in the atmosphere, and changed into oxygen and hydrogen gas. But is it true that a greater quantity of oxygen exists in the atmosphere after a long drought than immediately after rain? Have such prodigious quantities of hydrogen been found in the atmosphere as must always exist in it if this hypothesis were true? Has any hydrogen ever been found in analyzing atmospheric air? Or if hydrogen, from its lightness, ascends to the higher regions of the atmosphere, what causes it to descend at particular times, contrary to that lightness, in order to come into contact with oxygen? Do not clouds often form on mountains round the habitations of men? Yet has the presence of hydrogen been ever ascertained by any phenomena? Would it not produce dangerous conflagrations when it came into contact with fire? But has this been the case in a single instance? If this hypothesis were true, could rain take place at all without a conflagration in the atmosphere? Yet has any such conflagration been ever observed? The hypothesis, then, that vapour is changed into oxygen and hydrogen in the atmosphere, and that rain is produced by the reunion of these elements, cannot be admitted, though it is not improbable that some small part of it actually undergoes this change. See WIND.

We do not take notice of M. De Luc's conjecture about the composition of the atmosphere, because it is not supported by a single proof, and because he refuses to believe the analysis of the atmosphere resulting from the very decisive experiments of Scheele, Lavoisier, and Priestley, though he has seen them often performed, and has nothing to urge against their force. There is no philosopher to whom meteorology lies under greater obligations than to M. De Luc. His discoveries have been many and important, his experiments ingenious, and his application unwearied; but his conjectures are like those of every other man who attempts to fathom the wisdom of the Almighty. Were we possessed of an understanding equal to that of the Author of Nature, we might expect, with reason, to dive by our conjectures into the mysteries of his operations; but in our present state they are vain.

Evaporation goes on longest without producing rain in the torrid zone, where the heat is greatest; it goes on longest also in every place in summer, when the heat is also greatest: heat therefore seems to be an agent.

27
Theory of rain imperfect.

There are then two steps of the process between evaporation and rain, of which at present we are completely ignorant: 1. What becomes of the vapour after it enters into the atmosphere? 2. What makes it lay aside the new form which it must have assumed, and return again to its state of vapour, and fall down in rain? And till these two steps be discovered by experiments and observations, it will be impossible for us to give a rational or a useful theory of rain.

28
Whether owing to electricity.

It has for some time past been the opinion of philosophers, that electricity is the principal agent in producing rain; and M. Bertholon assures us, that by raising proper conductors to draw off the electrical matter from the atmosphere, the quantity of rain may be diminished at pleasure. That the electric fluid acts a very important part in nature, cannot be doubted, and it is not improbable that it may be the agent in producing rain. This supposition indeed is supported by many facts. Dew at least exhibits a great many electrical phenomena; it is attracted by points, and attaches itself to some substances, while it avoids others. Whenever there are no clouds, the electricity of the atmosphere is always positive; but the formation of clouds produces considerable

changes in the state of its electricity. The atmosphere also gives signs of electricity constantly during rain; and clouds are evidently attracted by mountains.—In what manner, however, the electrical fluid produces rain (if it is the agent at all) is still unknown. Some philosophers assure us, that clouds are induced to dissolve in rain by becoming negative, others by becoming strongly positive, and both support their opinion by experiments. We do not see the analogy, however, between clouds and plates of metal covered with drops of water. And even if their opinion were well founded, the production of the clouds themselves would remain to be accounted for.

The mean annual quantity of rain is greatest at the equator, and decreases gradually as we approach the poles.

Thus at * Granada, Antilles, 12° N. lat. it is 126 inches.

* Cape Francois, St Domingo	19° 46'	120
‡ Calcutta	22 23	81
* Rome	41 54	39
England	33	32
¶ Peterburgh	59 16	16

On the contrary, the number of rainy days is smallest at the equator, and increases in proportion to the distance from it. From north latitude 12° to 43° the mean number of rainy days is 78; from 43° to 46° the mean number is 103; from 46° to 50° it is 134; from 51° to 60°, 161 †.

The number of rainy days is often greater in winter than in summer; but the quantity of rain is greater in summer than in winter ‡. At Peterburgh, the number of rainy or snowy days during winter is 84, and the quantity which falls is only about five inches; during summer the number of rainy days is nearly the same, but the quantity which falls is about 11 inches ||.

More rain falls in mountainous countries than in plains. Among the Andes it is said to rain almost perpetually, while in Egypt it hardly ever rains at all.—If a rain-gauge be placed on the ground, and another at some height perpendicularly above it, more rain will be collected into the lower than into the higher; a proof that the quantity of rain increases as it descends, owing perhaps to the drops attracting vapour during their passage through the lower strata of the atmosphere where the greatest quantity resides. This, however, is not always the case, as Mr Copland of Dumfries discovered in the course of his experiments*. He observed also, that when the quantity of rain collected in the lower gauge was greatest, the rain commonly continued for some time; and that the greatest quantity was collected in the higher gauge only either at the end of great rains, or during rains which did not last long. These observations are important, and may, if followed out, give us new knowledge of the causes of rain. They seem to show, that during rain the atmosphere is somehow or other brought into a state which induces it to part with its moisture; and that the rain continues as long as this state continues. Were a sufficient number of observations made on this subject in different places, and were the atmosphere carefully analysed during dry weather, during rain, and immediately after rain, we might soon perhaps discover the true theory of rain.

Rain falls in all seasons of the year, at all times of the day, and during the night as well as the day; though, according to M. Toaldo, a greater quantity falls during the day than the night. The cause of rain, then, whatever it may be, must be something which operates at all times and seasons. Rain falls also during the continuance of every wind, but oftener when the wind blows from the south. Falls of rain often happen likewise during perfect calms.

It appears from a paper published by M. Cotte in the *Journal de Physique* for October 1791, containing the mean quantity of rain falling at 147 places, situated between north latitude 11° and 60°, deduced from tables kept at these places, that the mean annual quantity of rain falling in all these places is 34.7 inches. Let us suppose then (which cannot be very far from the truth) that the mean annual quantity of rain for the whole globe is 34 inches. The superficies of the globe consists of 170,981,012 square miles, or 686,401,498,471,475,200 square inches. The quantity of rain therefore falling annually will amount to 23,337,650,812,030,156,800 cubic inches, or somewhat more than 91,751 cubic miles of water. This is 16,191 cubic miles of water less than the quantity of water evaporated. It seems probable therefore, if the imperfection of our data warrant any conclusion, that some of the vapour is actually decomposed in the atmosphere, and converted into oxygen and hydrogen gas.

The dry land amounts to 52,745,253 square miles (see the article SEA, n° 1.); the quantity of rain falling on it annually therefore will amount to 30,960 cubic miles. The quantity of water running annually into the sea (see SEA, n° 3.) is 13,140 cubic miles; a quantity of water equal to which must be supplied by evaporation from the sea, otherwise the land would soon be completely drained of its moisture.

The quantity of rain falling annually in Great Britain may be seen from the following table :

In this country it generally rains less in March than in November, in the proportion at a medium of 7 to 12. It generally rains less in April than October in the proportion of 1 to 2 nearly at a medium. It generally rains less in May than September, the chances that it does so are at least as 4 to 3; but when it rains plentifully in May (as 1.8 inches or more), it generally rains but little in September; and when it rains one inch or less in May, it rains plentifully in September*.

IV. Thunder has been explained at such great length in the article ELECTRICITY, that we shall content ourselves at present with a few remarks.

Thunder is exceedingly frequent in the torrid zone, and it seems to decrease gradually till we approach latitude 60°, or perhaps farther north. During the year 1785, for in-

stance, there were 90 thunder-storms at Calcutta. According to Professor Muschenbroek, it thunders at Utrecht at a medium 15 times annually: in this country the medium is considerably below that number. Thunder, too, seems to be very common in some polar regions. The Abbé Chappe informs us, that he observed thunder much more frequently at Tobolski and in other parts of Siberia than in any other country. Muschenbroek, however, affirms, we know not upon what authority, that it never thunders at all in Greenland and at Hudson's Bay. Thunder-storms happen almost always during the summer, and very seldom in winter. During the year 1785 above mentioned, it never thundered at Calcutta in January, November, nor December. In this country a thunder-storm during winter is exceedingly rare.

The phenomena of thunder are now no longer a secret, since the great Franklin discovered the identity of lightning and electricity; a discovery inferior to none in the annals of philosophy. But though we can explain the nature of thunder in general, and the manner in which it is produced, there are several difficulties still remaining, which future experiments and observations only can remove. Air is an electric matter *per se*, and cannot therefore when dry conduct electrical matter from one part to another. We know from the experiments of Dr Franklin and others, that the atmosphere constantly contains in it a quantity of electric matter. If a stratum of dry air were electrified positively, it would occasion a negative electricity in the neighbouring stratum. Suppose now that an imperfect conductor were to come into contact with each of these strata, we know from the principles of electricity that the equilibrium would be restored, and that this would be attended with a loud noise, and with a flash of light. Clouds which consist of vesicular vapours mixed with particles of air, are imperfect conductors; if a cloud therefore come into contact with two such strata, a thunder clap would follow. If a positive stratum be situated near the earth, the intervention of a cloud will, by serving as a stepping-stone, bring the stratum within the striking distance, and a thunder clap will be heard while the electrical fluid is discharging itself into the earth. If the stratum be negative, the contrary effects will take place. It does not appear, however, that thunder is often occasioned by a discharge of electric matter from the earth into the atmosphere. The accidents, most of them at least, which were formerly ascribed to this cause, are now much more satisfactorily accounted for by Lord Stanhope's Theory of the Returning Stroke. Neither does it appear that electricity is often discharged into the earth, as the effects of few thunder-storms are visible upon the earth; that it is so sometimes, however, is certain. The experiments of Mr Saussure have demonstrated, that electrical matter is carried into the atmosphere by simple evaporation; so that there is no difficulty in understanding how particular strata of air may be supplied with a sufficient quantity of electrical fluid to be charged positively; and we know that in that case a negative state must be produced in the neighbouring stratum. In what particular manner, however, this electrical matter is accumulated in particular strata of air, and how it comes to be separated from the vapour to which it was united, remain still secrets. They are intimately connected with the causes of evaporation and rain, whatever they may be, and probably the discovery of the causes of either would lead to that of the others.

V. The gravity of the atmosphere was first demonstrated by Torricelli, the disciple of Galileo (see PNEUMATICS, ^{Of the changes in} the GRAVITY of the ^{atmosphere.} n° 25). A column of air, the basis of which is a square inch, weighs at a medium 15 pounds. The weight of the atmosphere is measured by the barometer. It is greatest ^{at}

Weather. at the level of the sea, because there the column of air is longest: there the mean height of the barometer is 30 inches. This Sir George Shuckburgh found to be the case in the Mediterranean and the Channel, in the temperature of 55° and 60°; Mr Bouguer, on the coast of Peru, in the temperature of 84°; and Lord Mulgrave, in latitude 80°. The mean height of the barometer is less the higher any place is situated above the level of the sea, because the column of air which supports the mercury is the shorter. The barometer has accordingly been used for measuring heights. It indicates, too, with a great deal of accuracy, all the variations in the gravity of the atmosphere; falling when the atmosphere is lighter, and rising when it is heavier, than usual. These changes have attracted the attention of philosophers ever since the discovery of the barometer; and many attempts have been made to explain them, some of which have been mentioned under the word BAROMETER. These variations come naturally to be examined here, because the causes which produce them, whatever they are, must have a great deal of influence on the weather.

Range of
the baro-
meter.

Between the tropics the variations of the barometer are exceedingly small; and it is remarkable, that in that part of the world it does not descend above half as much for every 200 feet of elevation as it does beyond the tropics*.— In the torrid zone, too, the barometer is elevated about two-thirds of a line twice every day; and this elevation happens at the same time with the tides of the sea †.

As the latitude advances towards the poles, the range of the barometer gradually increases, till at last it amounts to two or three inches. This gradual increase will appear from the following table:

TABLE of the Range of the Barometer.

In North America, however, the range of the barometer is a great deal less than in the corresponding European latitudes. In Virginia, for instance, it never exceeds 1.1 ¶. The range of the barometer is greater at the level of the sea than on mountains, and in the same degree of latitude the extent of the range is in the inverse ratio of the height of the place above the level of the sea.

From a table published by Mr Cotte in the *Journal de Physique* †, it seems exceedingly probable that the barometer has always a tendency to rise from the morning to the evening; and that this tendency is greatest between two o'clock in the afternoon and nine at night, at which hour the greatest elevation takes place; that the elevation of nine o'clock differs from that of two by $\frac{4}{12}$ ths, while that at two differs from the morning elevation only by $\frac{1}{12}$ th; and that in certain climates the greatest elevation takes place at two o'clock. We shall insert a part of the table on which these observations are founded, which we have reduced to the English Standard.

The range of the barometer is greater in winter than in summer. Thus at Kendal the mean range of the barometer for five years, during October, November, December, January, February, March, was 7.982; and for the six summer months 5.447*.

In serene and settled weather it is generally high; and low in calm weather, when the air is inclined to rain; it sinks on high winds, rises highest on easterly and northerly winds, and sinks when the wind blows from the south †.— At Calcutta ‡, however, it is always highest when the wind blows from the north-west and north, and lowest when it blows from the south-east.

The barometer falls suddenly before tempests, and undergoes great oscillations during their continuance.—Mr Copland § of Dumfries has remarked, that a high barometer is attended with a temperature above, and a low barometer with one below, the monthly mean.—Such are the variations of the barometer as far as they have yet been observed. Let us now endeavour to account for them as well as we can.

It is evident that the density of the atmosphere is least at the equator, and greatest at the poles; for at the equator the centrifugal force, the distance from the centre of the earth, and the heat, all of which tend to diminish the density of the air, are at their maximum, while at the pole they are at their minimum. The mean height of the barometer at the level of the sea, all over the globe, is 30 inches; the weight of the atmosphere, therefore, is the same all over the globe. The weight of the atmosphere depends on its density and height: where the density of the atmosphere is greatest, its height must be least; and, on the contrary, where its density is least, its height must be greatest. The height of the atmosphere, therefore, must be greatest at the equator, and least at the poles; and it must decrease gradually between the equator and the poles, so that its upper surface will resemble two inclined planes, meeting above the equator their highest part*.

During summer, when the sun is in our hemisphere, the

mean heat between the equator and the pole does not differ so much as in winter. Indeed the heat of northern countries at that time equals the heat of the torrid zone: thus in Russia, during July and August, the thermometer rises to 85° †. Hence the rarity of the atmosphere at the pole, and consequently its height, will be increased. The upper surface of the atmosphere, therefore, in the northern hemisphere will be less inclined; while that of the southern hemisphere, from contrary causes, will be much more inclined. The very reverse will take place during our winter.

The density of the atmosphere depends in a great measure on the pressure of the superincumbent column, and therefore decreases, according to the height, as the pressure of the superincumbent column constantly decreases. But the density of the atmosphere in the torrid zone will not decrease so fast as in the temperate and frigid zones; because its column is longer, and because there is a greater proportion of air in the higher part of this column. This accounts for the observation of Mr Cassan, that the barometer only sinks half as much for every 200 feet of elevation in the torrid as in the temperate zones (b). The density of the atmosphere at the equator, therefore, though at the surface of the earth it is less, must at a certain height equal, and at a still greater surpass, the density of the atmosphere in the temperate zones and at the poles.

In the article WIND we shall endeavour to prove, that a quantity of air is constantly ascending at the equator, and that part of it at least reaches and continues in the higher parts of the atmosphere. From the fluidity of air, it is evident that it cannot accumulate above the equator, but must roll down the inclined plane (c) which the upper surface of the atmosphere assumes towards the poles. As the surface of the atmosphere of the northern hemisphere is more inclined during our winter than that of the southern hemisphere, a greater quantity of the equatorial current of air must flow over upon the northern than upon the southern atmosphere; so that the quantity of our atmosphere will be greater during winter than that of the southern hemisphere: but during summer the very reverse will take place. Hence the greatest mercurial heights take place during winter, and the range of the barometer is less in summer than in winter.

The density of the atmosphere is in a great measure regulated by the heat of the place: wherever the cold is greatest, there the density of the atmosphere will be greatest, and its column shortest. High countries, and ranges of lofty mountains, the tops of which are covered with snow the greatest part of the year, must be much colder than other places situated in the same degree of latitude, and consequently the column of air over them much shorter. The current of superior air will linger and accumulate over these places in its passage towards the poles, and thus occasion an irregularity in its motion, which will produce a similar irregularity in the barometer. Such accumulations will be formed over the north-western parts of Asia, and over North America: hence the barometer usually stands higher, and varies less there, than in Europe. Accumulations are also formed upon the Pyrenees, the Alps, the mountains of Africa, Turkey in Europe, Tartary, and Tibet. When these accumulations have gone on for some

time, the density of the air becomes too great to be balanced by the surrounding atmosphere; it rushes down on the neighbouring countries, and produces cold winds which raise the barometer. Hence the rise of the barometer which generally attends north-east winds in Europe, as they proceed from accumulations in the north-west of Asia, or about the pole; hence, too, the north-west wind from the mountains of Tibet raises the barometer at Calcutta.

We shall endeavour to prove in the article WIND, that considerable quantities of air are occasionally destroyed in the polar regions. When this happens, the atmosphere to the south rushes in to fill up the void. Hence south-west winds take place, and the barometer falls.

As the mean heat of our hemisphere differs in different years, the density of the atmosphere, and consequently the quantity of equatorial air which flows towards the poles, must also be variable. Hence the range of the barometer is different in different years. Does this range correspond to the mean annual heat; that is to say, is the range greatest when the heat is least, and least when the heat is greatest? In some years greater accumulations than usual take place in the mountainous parts in the south of Europe and Asia, owing, perhaps, to earlier falls of snow, or to the rays of the sun having been excluded by long continued fogs. When this takes place, the atmosphere in the polar regions, will be proportionably lighter. Hence the prevalence of southerly winds during some winters more than others.

As the heat in the torrid zone never differs much, the density, and consequently the height of the atmosphere, will not vary much. Hence the range of the barometer within the tropics is comparatively small; and it increases gradually as we approach the poles, because the difference of the temperature, and consequently of the density, of the atmosphere increases with the latitude.

The diurnal elevation of the barometer in the torrid zone corresponding to the tides, observed by Mr Cassan and others, must be owing to the influence of the moon on the atmosphere. This influence, notwithstanding the ingenious attempts of D'Alembert and several other philosophers, seems altogether inadequate to account for the various phenomena of the winds. It is not so easy to account for the tendency which the barometer has to rise as the day advances, which seems to be established by Mr Cotte's table. Perhaps it may be accounted for by the additional quantity of vapour added to the atmosphere, which, by increasing the quantity of the atmosphere, may possibly be adequate to produce the effect.

The falls of the barometer which precede, and the oscillations which accompany, violent storms and hurricanes, show us that these phenomena are produced by very great rarefactions, or perhaps destruction of air, in particular parts of the atmosphere. The falls of the barometer, too, that accompany winds proceed from the same cause. The observation made by Mr Copland, that a high barometer is accompanied by a temperature above the mean, will be easily accounted for by every one acquainted with Dr Black's theory of latent heat. The higher the mercury stands, the denser the atmosphere must be; and the denser it becomes, the more latent heat it must give out. It is well known that air evolves heat when condensed artificially.

Weather.

(b) Should it not be examined whether the number of parts which the mercury sinks for every 200 feet of elevation be not proportioned to the latitude of the place?

(c) It is of no consequence whether the surface of the atmosphere actually forms an inclined plane, or, becoming rarer in a very slow ratio (as is probably the case), ascends much higher than the place at which the equatorial currents begin to flow towards the poles; for still the different heights of air of the same density in different parts of the atmosphere will in fact form an inclined plane, over which these currents will roll, notwithstanding the very rare air which they may displace.

Weather. The falling of the barometer which generally precedes rain remains still to be accounted for; but we know too little about the causes by which rain is produced to be able to account for it in a satisfactory manner. Probably a rarified state of the atmosphere is favourable to the production of rain; we know, at least, that it is favourable to evaporation. Supposing the observations which we made upon the changes which vapour undergoes in the atmosphere well founded, may not the vapour in its new form accumulate at a considerable height in the atmosphere? and is not the height at which clouds are always formed a proof of this? May not this substance, whatever it is, when by some means or other it returns to the state of vapour, passes its maximum, and begins to fall in drops of rain, and consequently is no longer supported by the atmosphere, cause the barometer to fall suddenly, at least till new air rushes in to supply its place?

⁴⁰
OF PROG-
NOSTICA-
TING THE
WEATHER.

Thus we have endeavoured to describe the various phenomena of the weather, and to account for them as far as the present state of our meteorological knowledge enables us to go.

It will be expected that we should not pass by unnoticed that branch of meteorology which has in all ages attracted the attention of mankind, and in which, indeed, every other part of the science, as far as utility is concerned, evidently centres; we mean the method of prognosticating the weather. All philosophers who have dedicated their attention to meteorology, have built upon the hope of being able to discover, by repeated observations, some rules concerning the periods of the seasons and the changes of the weather, convinced that such discoveries would be of the highest utility, especially in agriculture; for by foreseeing, even in part, the circumstances of the seasons, we would have it in our power to prevent at least a part of the losses arising from them, as by sowing, for instance, the kind of corn best adapted for the rain or the drought which is to ensue.

⁴¹
Moon sup-
posed to
influence
the weat-
her;

The influence of the moon on the weather has in all ages been believed by the common people; the ancient philosophers embraced the same opinion, and congratulated upon it their pretended science of astrology. Several modern philosophers have thought the opinion worthy of notice; among whom Messrs Lambert, Cotte, and Toaldo, deservedly take the lead. These philosophers, after examining the subject with the greatest attention, have embraced the opinion of the common people, though not in its full extent. To this they have been induced both by the certainty that the moon actually has an influence on the atmosphere as it has on the sea, and by observing that certain situations of the moon in her orbit have almost constantly been attended with changes of the weather either to wind, to calm, to rain, or to drought.

⁴²
Especially
in ten situa-
tions,

There are ten situations in every revolution of the moon in her orbit, when she must particularly exert her influence on the atmosphere, and when consequently changes of the weather most readily take place. These are (1) the new and (2) full moon, when she exerts her influence in conjunction with or opposition to the sun; (3 and 4) the quadratures; (5) the perigee and (6) apogee (for the difference in the moon's distance from the earth is about 27,000 miles), the two passages of the moon over the equator, one of which, Mr Toaldo calls (7) the moon's ascending, and (8) the other the moon's descending equinox, the two lunifications as M. de la Lande has called them, (9) the boreal lunification, when the moon approaches as near as she can in each lunation to our

zenith, (10) the austral, when she is at the greatest distance from it, for the action of the moon varies greatly according to her obliquity. With these ten points Mr Toaldo compared a table of 48 years observations for Lombardy, and found the result as follows;

Lunar Points.	Attended with a change of weather.	Attended with no change.	Proportion reduced to the lowest terms.
New moons - -	522	82	6 : 1
Full moons - - -	506	92	5 : 1
First quarters	424	189	2 $\frac{1}{2}$: 1
Last quarters - -	429	182	2 $\frac{1}{2}$: 1
Perigees - -	546	99	7 : 1
Apogees - - -	517	130	4 : 1
Ascending equinoxes	465	142	3 $\frac{1}{2}$: 1
Descending equinoxes	446	152	2 $\frac{3}{4}$: 1
Southern lunifications	446	154	3 : 1
Northern lunifications	448	162	2 $\frac{1}{2}$: 1

And after examining a number of other tables of observations, and combining them with his own, he found the proportions between those lunar points on which changes of the weather took place, and those which passed without any change when reduced to the lowest terms, to be as in the last column of the above table: so that we may wager six to one, that this or that new moon will bring a change of weather, and five to one that a full moon will be attended by a change, and so on. Several of these lunar points often coincide with one another, occasioned by the inequality of the moon's periodical, anomalistical, and synodical revolutions, and by the progressive motion of the apses. Thus the new and full moon sometimes coincide with the apogees, the perigees, &c. These coincidences are the most efficacious. Their changing power, according to Mr Toaldo, is as follows:

New moon coinciding with the perigee	33 : 1
-----with the apogee	7 : 1
Full moon coinciding with the perigee	10 : 1
-----with the apogee	8 : 1

It ought to be remarked, that these changes of the weather seldom or never take place exactly when the moon is in these lunar points, but some time before or after; just as the tide, say the philosophers who contend for the influence of the moon, is not at its height till after the moon has passed the meridian.

The power of the moon over the ocean and the atmosphere is displayed in a particular manner during the apses, in consequence of her different distances from the earth during these two situations. Now the apses advance about 40° in the zodiac every year, and complete a revolution in about eight years and ten months. It is probable that the seasons and the constitutions of years have a period nearly equal to this revolution, and that therefore nearly the same seasons return every ten years. This periodical return of the seasons, as Pliny (b) seems to inform us, was observed by the ancients. Mr Toaldo found, that in Lombardy the quantities of rain which fell during periods of nine successive years were nearly equal; but that this was not true of other periods, for instance, of six, eight, or ten years. By comparing in like manner the quantities of rain published by the Royal Academy of Sciences at Paris, from 1699 to 1752, he found, that

⁴³
And to
cation a
riod of 10
years,

(b) "Tempestates ardores suos habere quadris annis.—Ostonsis vero augeri easdem centesima revolventi sc luna."
Lib. 18. c. 25.

her. that of six series of nine years, three were greater and three smaller, but on both sides almost equal to one another.

During the revolution of the apses, there are four remarkable points, the two equinoctial and two solstitial points; in which, when the moon is in perigee, her effect will be most powerful on the weather. The moon passes from one equinoctial point to another in about four years; in them its power is greatest: it is probable, therefore, that when an extraordinary year happens, a return of another may be expected in about four years. As the apses after their revolution return again in the same order as before, it is probable that the return of the seasons will be nearly the same in every series of nine years.

Such, according to Mr Toaldo, is the period at the end of which we are to expect a return of the seasons. Mr Cotte, however, though he does not deny the influence of the revolution of the apses, places greater confidence in the lunar period of 19 years; at the end of which, the new and full moons return to the same day in the Julian year. He supposes, that in like manner the seasons correspond with one another every 19 years. The similarity, he informs us, is striking between the temperatures of the years 1701, 1720, 1739, 1758, and 1777. That of 1758, upon which we have observations much detailed by M. du Hamel, has a remarkable coincidence with 1777; there was scarcely any difference in the temperatures of the corresponding months. The years 1778, 1779, and 1780, have been hot and dry, and they correspond with years which have had the same character. The years corresponding with 1782, especially 1725 and 1763, have been singularly cold, humid, and late, as was the case with 1782 †.

Such is an imperfect view of the opinions of those philosophers who have endeavoured to establish the influence of the moon over the weather. The most important of their maxims for prognosticating the weather are the following:

1. When the moon is in any of the ten lunar points above mentioned, a change of the weather may be expected. The most efficacious of these points are the conjunctions and apses.
2. The coincidence of the conjunctions with the apses is extremely efficacious: that of the new moon with the perigee gives a moral certainty of a great perturbation.
3. The new and full moons, which sometimes produce no change on the weather, are such as are at a distance from the apses.
4. A lunar point commonly changes the state into which the weather was brought by the preceding point. For the most part the weather never changes but with some lunar point.
5. The apogees, quadratures, and southern lunifications, commonly bring fair weather, for the barometer then rises; the other points tend to make the air lighter, and thereby to produce bad weather.
6. The most efficacious lunar points become stormy about the equinoxes and solstices.
7. A change of weather seldom happens on the same day with a lunar point, but sometimes before and sometimes after it.
8. At the new and full moons about the equinoxes, and even the solstices, especially the winter solstice, the weather is commonly determined to good or bad for three, or even six months.
9. The seasons and years have a period of eight or nine years corresponding with the revolution of the lunar apses, and another of 19 corresponding to the lunar period.

Would it not be worth while to publish a meteorological kalendar yearly, marking the time, to which the lunar points correspond, at which changes of the weather may be expect-

ed, especially when any of these points coincide; and marking the probability of a change at any particular time? and might not this be attended by a diary of the weather for the 9 or 19 corresponding years? By this means, if there is any probability in the opinion that the moon has influence over the weather, men would be enabled to foresee changes with a considerable degree of probability; and at any rate, we would be able, by the united observations of a whole nation, to determine whether there be any truth in the opinion; and if there be, as its universality would lead one to suppose, succeeding observations would gradually correct the imperfection of our present rules, and enable us to bring our prognostics of the weather to the greatest exactness.

We are not so sanguine, however, as Mr Toaldo and P. Cotte on this subject. Even allowing the influence of the moon on the weather to be as great as they could desire, and supposing, which is very far from being the case, that it is not influenced by any other cause, we do not see how the seasons could return in the same order every 9th or 19th year. The motions of the heavenly bodies (especially the moon) are, strictly speaking, incommensurable. The lunar apogee returns to the same situation in eight years ten months (without reckoning hours and minutes): at its first return it will be two months or signs removed from the same situation with the sun; at the end of the second period, four months; and at the end of the third, six months; so that if the season was winter at the beginning, after three revolutions it will be the middle of summer. Now, how in this case can the same seasons return? Supposing the equinoctial points to produce constantly great changes on the weather, if one of them during the first revolution happened in winter, in the second it would happen in spring, and the third in summer; so that what would during the first revolution produce a particular winter, would in the second act upon the spring, and in the third on the summer. Would it in these cases produce similar changes on the weather? Surely not. And whether it did or not, would the same seasons return in every revolution? In six complete revolutions, indeed, or 53 years, the lunar perigee returns to the same situation as at first, very nearly, in the same season: it might be expected then that the seasons would perform a complete revolution every 53 years, and that the 54th would exactly resemble the first, and so on. This may possibly be the case, but it is by no means probable; for when Mr Toaldo compared the quantity of rain which fell at Paris during 1699, 1700, 1701, 1702, &c. with what fell in 1752, 1753, 1754, &c. though the first years in each series corresponded pretty exactly, the difference being only eight lines, there was no such resemblance between any of the following years.

Neither are we convinced that the influence of the moon can have such an effect on the weather as the above mentioned philosophers suppose. The moon only acts, as far as we know at least, by producing tides in the atmosphere; for the refined speculations of Mr Toaldo about its electrical influence we cannot admit, as the electricity of the atmosphere is less during the night, when the moon's influence should be greatest, than during the day. Now we do not see how these tides, supposing them greater than they are, can be adequate to the effects ascribed to them.

Mr Kirwan † has lately endeavoured to discover probable rules for prognosticating the different seasons, as far as regards Britain and Ireland, from tables of observations alone. On perusing a number of observations, taken in England from 1677 to 1789, he found,

1. That when there has been no storm before or after the vernal equinox, the ensuing summer is generally dry at least five times in six.

- Weather.** 2. That when a storm happens from an easterly point, either on the 19th, 20th, or 21st of May, the succeeding summer is generally *dry* four times in five.
3. That when a storm arises on the 25th, 26th, or 27th of March (and not before), in any point, the succeeding summer is generally *dry* four times in five.
4. If there be a storm at south-west or west-south-west on the 19th, 20th, 21st, or 22d of March the succeeding summer is generally *wet* five times in six.

In this country winters and springs, if dry, are most commonly cold; if moist, warm: on the contrary, dry summers and autumns are usually hot, and moist summers cold. So that if we know the moistness or dryness of a season, we can judge pretty accurately of its temperature.

From a table of the weather kept by Dr Rutton, in Dublin, for 41 years, Mr Kirwan endeavoured to calculate the probabilities of particular seasons being followed by others. Though his rules relate chiefly to the climate of Ireland, yet as probably there is not much difference between that island and Britain in the general appearance of the seasons, we shall mention his conclusions here.

In 41 years there were 6 wet springs, 22 dry, and 13 variable; 20 wet summers, 16 dry, and 5 variable; 11 wet autumns, 11 dry, and 19 variable. A season, according to Mr Kirwan, is counted *wet* when it contains two wet months. In general the quantity of rain which falls in dry seasons is less than five inches, in wet seasons more: variable seasons are those in which there falls between 30lb. and 36lb. a lb. being equal to .157639 of an inch.

The order in which the different seasons followed each other was as in the following table:

Season	Probability	Times
A dry spring	$\frac{1}{8}$	8
A wet spring	$\frac{3}{8}$	3
A variable spring	$\frac{1}{2}$	5
A dry summer	$\frac{1}{5}$	5
A wet summer	$\frac{2}{5}$	12
A variable summer	$\frac{1}{5}$	3
A dry spring and dry summer	$\frac{1}{4}$	4
A dry spring and wet summer	$\frac{1}{4}$	2
A wet spring and dry summer	$\frac{1}{4}$	0
A wet spring and wet summer	$\frac{1}{4}$	1
A wet spring and variable summer	$\frac{1}{4}$	1
A dry spring and variable summer	$\frac{1}{4}$	2

Season	Probability	Times
A variable spring and dry summer	$\frac{1}{2}$	2
A variable spring and wet summer	$\frac{1}{2}$	1
A variable spring and variable summer	$\frac{1}{2}$	5

Hence Mr Kirwan deduced the probability of the kind of seasons which would follow others. This probability is expressed in the last column of the table, and is to be understood in this manner: The probability that a dry summer will follow a dry spring is $\frac{1}{2}$; that a wet summer will follow a dry spring $\frac{1}{2}$; that a variable summer will follow a dry spring $\frac{1}{2}$; and so on.

This method of Mr Kirwan, if there is such a connection between the different seasons that a particular kind of weather in one has a tendency to produce a particular kind of weather in the next, as it is reasonable to expect from theory, may in time, by multiplying observations, come to a great degree of accuracy, and may at last, perhaps, lead to that great desideratum, a rational theory of the weather. As we wish to throw as much light as possible on this important subject, we shall add to these a few maxims, the truth of which have either been confirmed by long observation, or which the knowledge we have already acquired of the causes of the weather has established on tolerably good grounds.

1. A moist autumn with a mild winter is generally followed by a cold and dry spring, which greatly retards vegetation.—Such was the year 1741*.

2. If the summer be remarkably rainy, it is probable that the ensuing winter will be severe; for the unusual evaporation will have carried off the heat of the earth. Wet summers are generally attended with an unusual quantity of seed on the white thorn and dog-rose bushes. Hence the unusual fruitfulness of these shrubs is a sign of a severe winter.

3. The appearance of cranes and birds of passage early in autumn announces a very severe winter; for it is a sign that it has already begun in the northern countries.

4. When it rains plentifully in May, it will rain but little in September, and *vice versa*.

5. When the wind is south-west during summer or autumn, and the temperature of the air unusually cold for the season, both to the feeling and the thermometer, with a low barometer, much rain is to be expected †.

6. Violent temperatures, as storms or great rains, produce a sort of crisis in the atmosphere, which produces a constant temperature, good or bad, for some months ††.

7. A rainy winter predicts a sterile year.—A severe autumn announces a windy winter †††.

Thus we have endeavoured to describe the various phenomena of the weather, and to explain them as far as the infant state of our knowledge of the atmosphere furnished us with principles.

Notwithstanding the imperfection of our present knowledge of this subject, the numbers and the abilities of the philosophers who are at present engaged in the study cannot fail at last of being crowned with success; and perhaps a rational and satisfactory theory of the weather is not so far distant as we at present suppose. It is a pity, however, that in a science attended with so much difficulty as meteorology is, various artificial difficulties should have been thrown in the way, which contribute very much to obstruct its progress. There are no fewer than four thermometers

ther meters used at present in different parts of Europe; and the observations made by each of them must be reduced to one common standard before it is possible to compare them with one another. This is a tedious enough business, but it is nothing at all to the reduction of observations of rain and of the barometer to one common standard. Every nation has its own peculiar measure; and the French, to add to the difficulty, have reckoned by lines, and twelfths of lines, instead of by decimal parts of an inch. Whether, however, this be the case at present or not, we know not, as we have seen no meteorological tables drawn up in France later than 1792. Philosophers ought certainly to fix upon some common standard of weights and measures, otherwise the labour in meteorology, and even in chemistry, must soon become intolerable. The only other possible way to remedy this evil would be, to construct accurate tables, in which the various weights and measures used by philosophers are reduced to one common standard. This has already been done in part; but no table of this kind which we have seen is sufficient to remedy the evil: few of them descend to decimal parts of small weights or measures; yet without this they seldom can save the trouble of calculation.

WEATHER, in sea-language, is used as an adjective, and applied by mariners to every thing lying to windward of a particular situation: thus, a ship is said to have the weather-gage of another, when she is farther to windward. Thus also, when a ship under sail presents either of her sides to the wind, it is then called the *weather-side* or *weather-board*; and all the rigging and furniture situated thereon are distinguished by the same epithet, as the *weather-shrouds*, the *weather-lifts*, the *weather-braces*, &c.

To **WEATHER**, in sea-language, is to sail to windward of some ship, bank, or head-land.

WEATHER-COCK, a moveable vane, in form of a cock, or other shape, placed on high, to be turned round according to the direction of the wind, and point out the quarter from whence it blows.

WEATHER-GLASS. See **BAROMETER**.

WEATHERING, among sailors, signifies the doubling or sailing by a head-land or other place.

WEAVING, the art of working a web of cloth, silk, or other stuff, in a loom with a shuttle. For an idea of the manner in which this is performed, see **CLOTH**.

WEAVING-LOOM, a machine for weaving cloth, silk, &c. by raising the threads of the warp in order to throw in the shoot, and strike it close. Of these there are various kinds, distinguished by the different sorts of cloths, stuffs, silks, &c. in which they are employed; and which are chiefly distinguished by the number and variety of the threads they raise in order to work the warp, either plain or in figures, by making more or less of the woof or shoot appear through the warp. In order to give a general idea of weaving, we shall here describe the parts of the common weaver's loom. See Plate DXXXIX. fig. 1. in which *ef*, *ef* are the front posts, and *g*, *g* the back posts of the loom; *lll*, *m m*, *m m* are the *lams* in their place at *Q*, or, as they are called in some parts of Scotland, the *biddles*, and in others the *flaves*. They are composed of strong threads, stretched between two horizontal bars, an upper and a lower. The threads of one lam are so disposed as to pass between the upper threads of the warp, while they admit the lower threads to pass through loops or small holes in them, and the disposition of the threads of the other lam is such, that while they pass between the lower threads of the warp, they admit the upper threads to pass through the small holes just mentioned. The lams are suspended from the cross bar or *lam-bearer* *HH*, by means of ropes *n*, *n* passing from the upper bars of

the *lams* over the pulleys at *EE*, and balanced by weights at the other ends. From the lower bar of each *lam* or *biddle* a rope passes to the *treadles* or moveable bars at *OO*; so that when a foot presses a treadle, the lam fastened to it sinks, while the other rises by means of the balancing weight suspended from the pulley at *E*. The workman then throws in the woof by means of the shuttle, and closes it by one or two strokes of the *lay* or *batten*, of which *WB*, *WB* are called the *swords*, *CC* the *cap*, or in Scotland the upper *shell*, *DD* the *block* or under *shell*, and *PP* the *reed* or *comb* contained between these shells. *LL* is the bench on which the workmen sit; for the loom which our figure represents is constructed for weaving cloth of such a breadth as to require two workmen, who have their quills in a box *d* on the middle of the bench on which they sit. Between the workmen's bench and the *batten* or *lay* is the *breast-bar* *I*, *I*, a smooth square beam, in which there is an opening to let the web through as it is wove. From this opening the web *SS* passes to the *knee roll* or *web beam* *GG*, round which it is rolled by means of the spokes, visible in the figure, and kept from being unrolled by a wheel with teeth and clench, visible likewise in the figure. In some looms the web passes from the knee-roll to the wooden frame *X*, to be dried as it is wove. Opposite to the breast-bar, and on the other side of the *batten* or *lay*, is the *cane-roll* or *yarn-beam*, on which the warp is rolled when put into the loom, and from which it is gradually unrolled as the work proceeds. *TT* are bobbins filled with yarn of the warp to mend such threads of it as may be broke in the weaving; and *Bb*, *Bb* are clues of the same kind of yarn with the borders of the warp, to mend such threads as may there be broken.

Fig. 2. represents the common shuttle with the vacuity in the middle, in which the quill with the woof is placed on a spindle or axis. As this shuttle is thrown with one hand in at one side of the warp, and received with the other hand at the other side, it is obvious, that when the web is of a breadth too great for a man to reach from one side of it to the other, two workmen must be employed and much time lost. To remedy this inconveniency, a new shuttle has, in this country, been lately brought into very general use, and called the *flying shuttle*, because it flies through the warp with wonderful rapidity on two steel rollers *RR* (fig. 3.) This shuttle is not thrown with the hand, but moved backwards and forwards by a very simple piece of machinery, of which fig. 4. will give the reader a sufficiently accurate conception. To each end of the *batten* or *lay* *L* is fastened a kind of open box *B*, *b*, with the bottom or horizontal side exactly on a level with the threads of the warp of the intended web. In each of these boxes is a vertical piece of wood *D*, *d*, of considerable thickness, called a *driver*. This driver is moved easily on an iron spindle or axis from one end of the box to the other by means of a slender rope *CCCD*, and a handle *H* is seen in the figure. When the weaver is to begin his work, he lays the shuttle on its rollers in the box *B* with the iron tip *T* (fig. 3.) touching, or almost touching, the driver *D* (fig. 4.) Then moving the handle *H*, with a sudden jerk, towards the box *b*, the driver *D* forces the shuttle with a rapid motion thro' the warp till it strikes *d*, which is impelled by the stroke to the further end of the box *b*. The two drivers *D* and *d* have now exchanged their positions in their respective boxes; so that the driver which was at the front of its box before, is now at the farther end of it, and *vice versa*. Then by a sudden jerk of the hand towards *B* the shuttle is driven back till it strike *D*; and thus is the work continued without the weaver having occasion ever to stretch his arms from one margin of the web to the other. That the shuttle may not, by the unsteadiness of the work-

Weaving.

Web
||
Weight

man's hand, be driven zig-zag through the warp or out of the place in which it ought to move, the guiding or driving rope CCCD is made to pass through smooth holes or loops C, C, at the ends of the ropes EC, EC, suspended either from the cross bar on the top of the loom or from the swords of the batten.

This shuttle, we should think, a great improvement in every kind of weaving loom, though some of the older tradesmen, with whom we have conversed on the subject, contend, that it is valuable only in what they call light work, such as cotton or linen cloth, or when the web, if woollen, is very broad.

WEB, a sort of tissue or texture formed of threads interwoven with each other; some whereof are extended in length, and called the *warp*; others are drawn across, and called the *woof*.

WEDGE, one of the mechanical powers. See MECHANICS.

WEDNESDAY, the fourth day of the week, so called from a Saxon idol named *Woden*, supposed to be Mars, worshipped on this day.

Abb. WEDNESDAY, the first day of Lent, so called from the custom observed in the ancient Christian church of penitents expressing their humiliation at this time, by appearing in sack cloth and ashes.

WEED, a common name for all rank and wild herbs, that grow of themselves, to the detriment of other useful herbs they grow among.

WEED, in the miners language, denotes the degeneracy of a load or vein of fine metal into an useless marcasite.

WEEDS, also denote a peculiar habit, worn by the relics of persons deceased, by way of mourning.

WEEK, in chronology, a division of time comprising seven days. See PLANETARY Days and SABBATH.

Passion-WEEK, or the *Holy WEEK*, is the last week in Lent, wherein the church celebrates the mystery of our Saviour's death and passion.

WEEK OF WYCK, in geography, a parliament and port-town of Scotland, in the shire of Caithness. W. Long. 3. 2. N. Lat. 58. 30.

Weeks Ember. See EMBER.

Fest of WEEKS. See PENTECOST.

WEEVEL, *Method of destroying.* See GRANARY.

WEEVER, in ichthyology. See TRACHINUS.

WEEVIL, in zoology, a species of curculio. See CURCULIO.

WEIGH, a weight of cheese, wool, &c. containing 256 pounds avoirdupois. Of corn, the weigh contains 40 bushels; of barley or malt, six quarters. In some places, as Essex, the weigh of cheese is 300 pounds.

WEIGHING, the act of examining a body in the balance to find its weight.

WEIGHING Anchor, is the drawing it out of the ground it had been cast into, in order to set sail, or quit a port, road, or the like.

WEIGHT, in physics, a quality in natural bodies, whereby they tend downwards towards the centre of the earth. Or, weight may be defined in a less limited manner, to be a power inherent in all bodies whereby they tend to some common point, called the *centre of gravity*, or, to speak more accurately, to one another: and that with a greater or less velocity, as they are more or less dense, or as the medium they pass through is more or less rare. See MECHANICS.

WEIGHT, in commerce, denotes a body of a known weight appointed to be put in the balance against other bodies whose weight is required.

The security of commerce depending, in a good measure, on the justness of weights, which are usually of lead, iron, or brass, most nations have taken care to prevent the falsification thereof, by stamping or marking them by proper officers, after being adjusted by some original standard. Thus, in England, the standard of weights is kept in the exchequer by a particular officer, called the *clerk of the market*.

Weights may be distinguished into ancient and modern.

I. ANCIENT WEIGHTS.

1. Those of the ancient Jews, reduced to the English troy weight, will stand as in the following table:

Shekel			lb.	oz.	dwt.	gr.
			0	0	9	2 ¹ / ₂
60	Maneh		2	3	6	10 ² / ₇
3000	50 Talent		113	10	1	10 ² / ₇

2. Roman weights, reduced to English troy weight, will stand as in the following table:

Lentes					oz.	dwt.	gr.
					0	0	0 ⁸⁵ / ₁₂₈
4	Siliquæ				0	0	3 ³ / ₈
12	3 Obolus				0	0	9 ³ / ₈
24	6 2	Scriptulum			0	0	18 ³ / ₄
72	18 6 3	Drachma			0	2	6 ² / ₃
96	24 8 4 1 ¹ / ₂	Sextula			0	3	0 ⁶ / ₇
144	36 12 6 2 1 ¹ / ₂	Sicilicus			0	4	13 ² / ₇
192	48 16 8 2 ¹ / ₂ 2 1 ¹ / ₂	Duella			0	6	1 ² / ₇
576	144 48 24 8 6 4 3	Uncia			0	18	5 ¹ / ₇
6912	1728 576 288 96 72 48 36 12	Libra			10	18	13 ² / ₇

The Roman ounce is the English avoirdupois ounce, which they divided into 7 denarii, as well as 8 drachmas.

3. Attic Weights.

Drachma				English Troy Weight
				lb. oz. dwt. gr.
				0 0 2 16.9
100	Mina			1 1 10 10
6000	60 Talent			67 7 5 0

II. MODERN WEIGHTS.

1. *English Weights.*— Mr Renardson, in a paper published in the Philosophical Transactions, has proved, that at first there was but one weight in England, and that this was the avoirdupois. Troy weight was introduced in the time of Henry VII: At present, both the troy and avoirdupois weights are used in England. Troy weight seems to have derived its name from *Troyes*, a town in France, where a celebrated fair was kept. It is used for weighing gold, silver, jewels, silk, and all liquors. The avoirdupois is used for weighing other things.

Fig. 1.

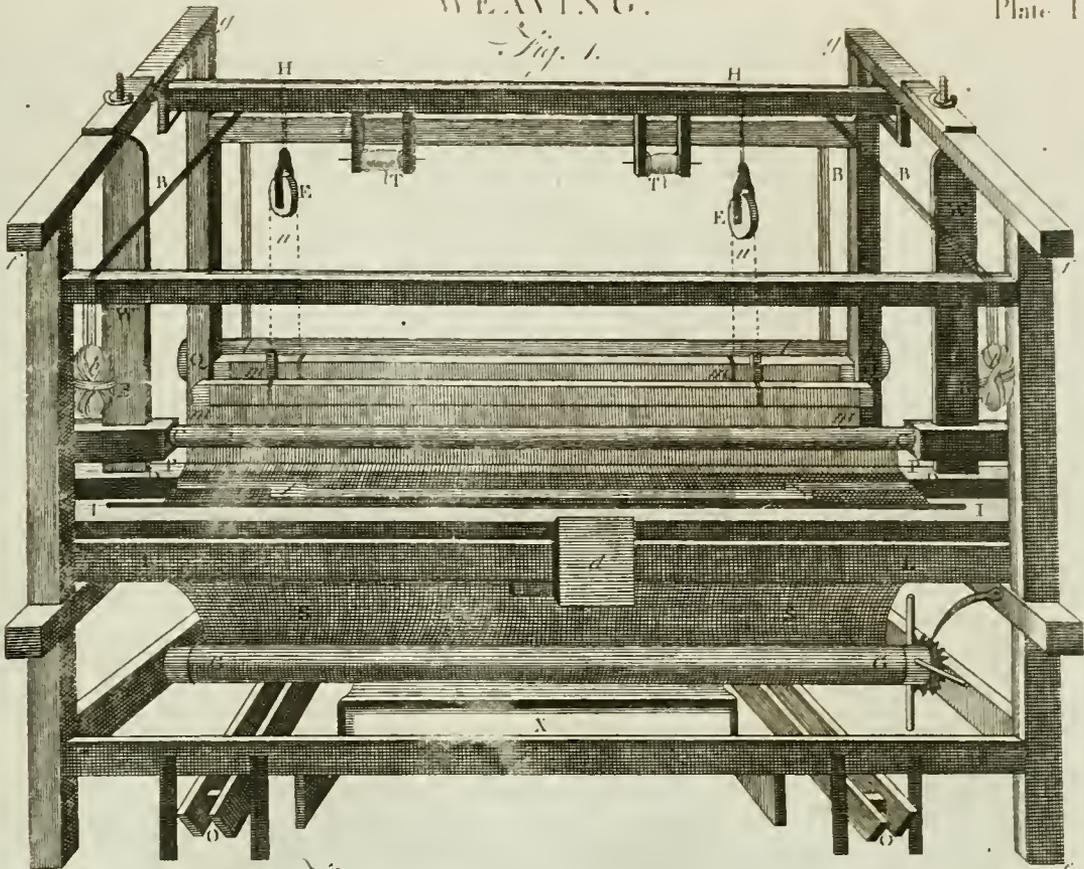

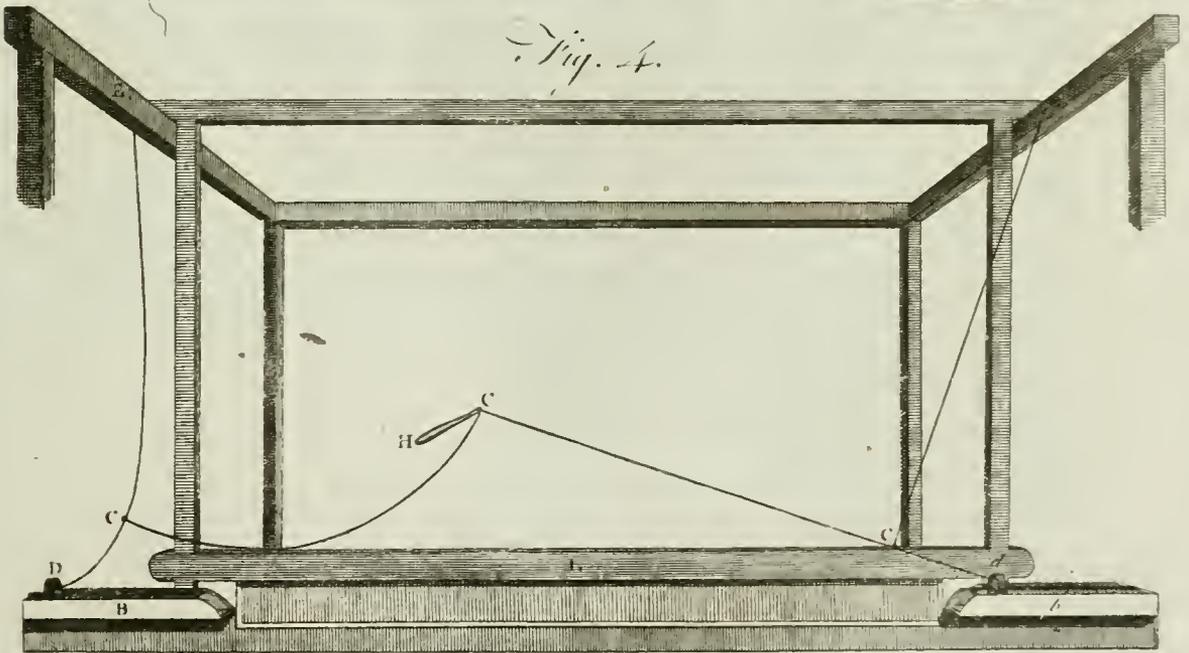

Fig. 3.

Fig. 2.

Fig. 4.

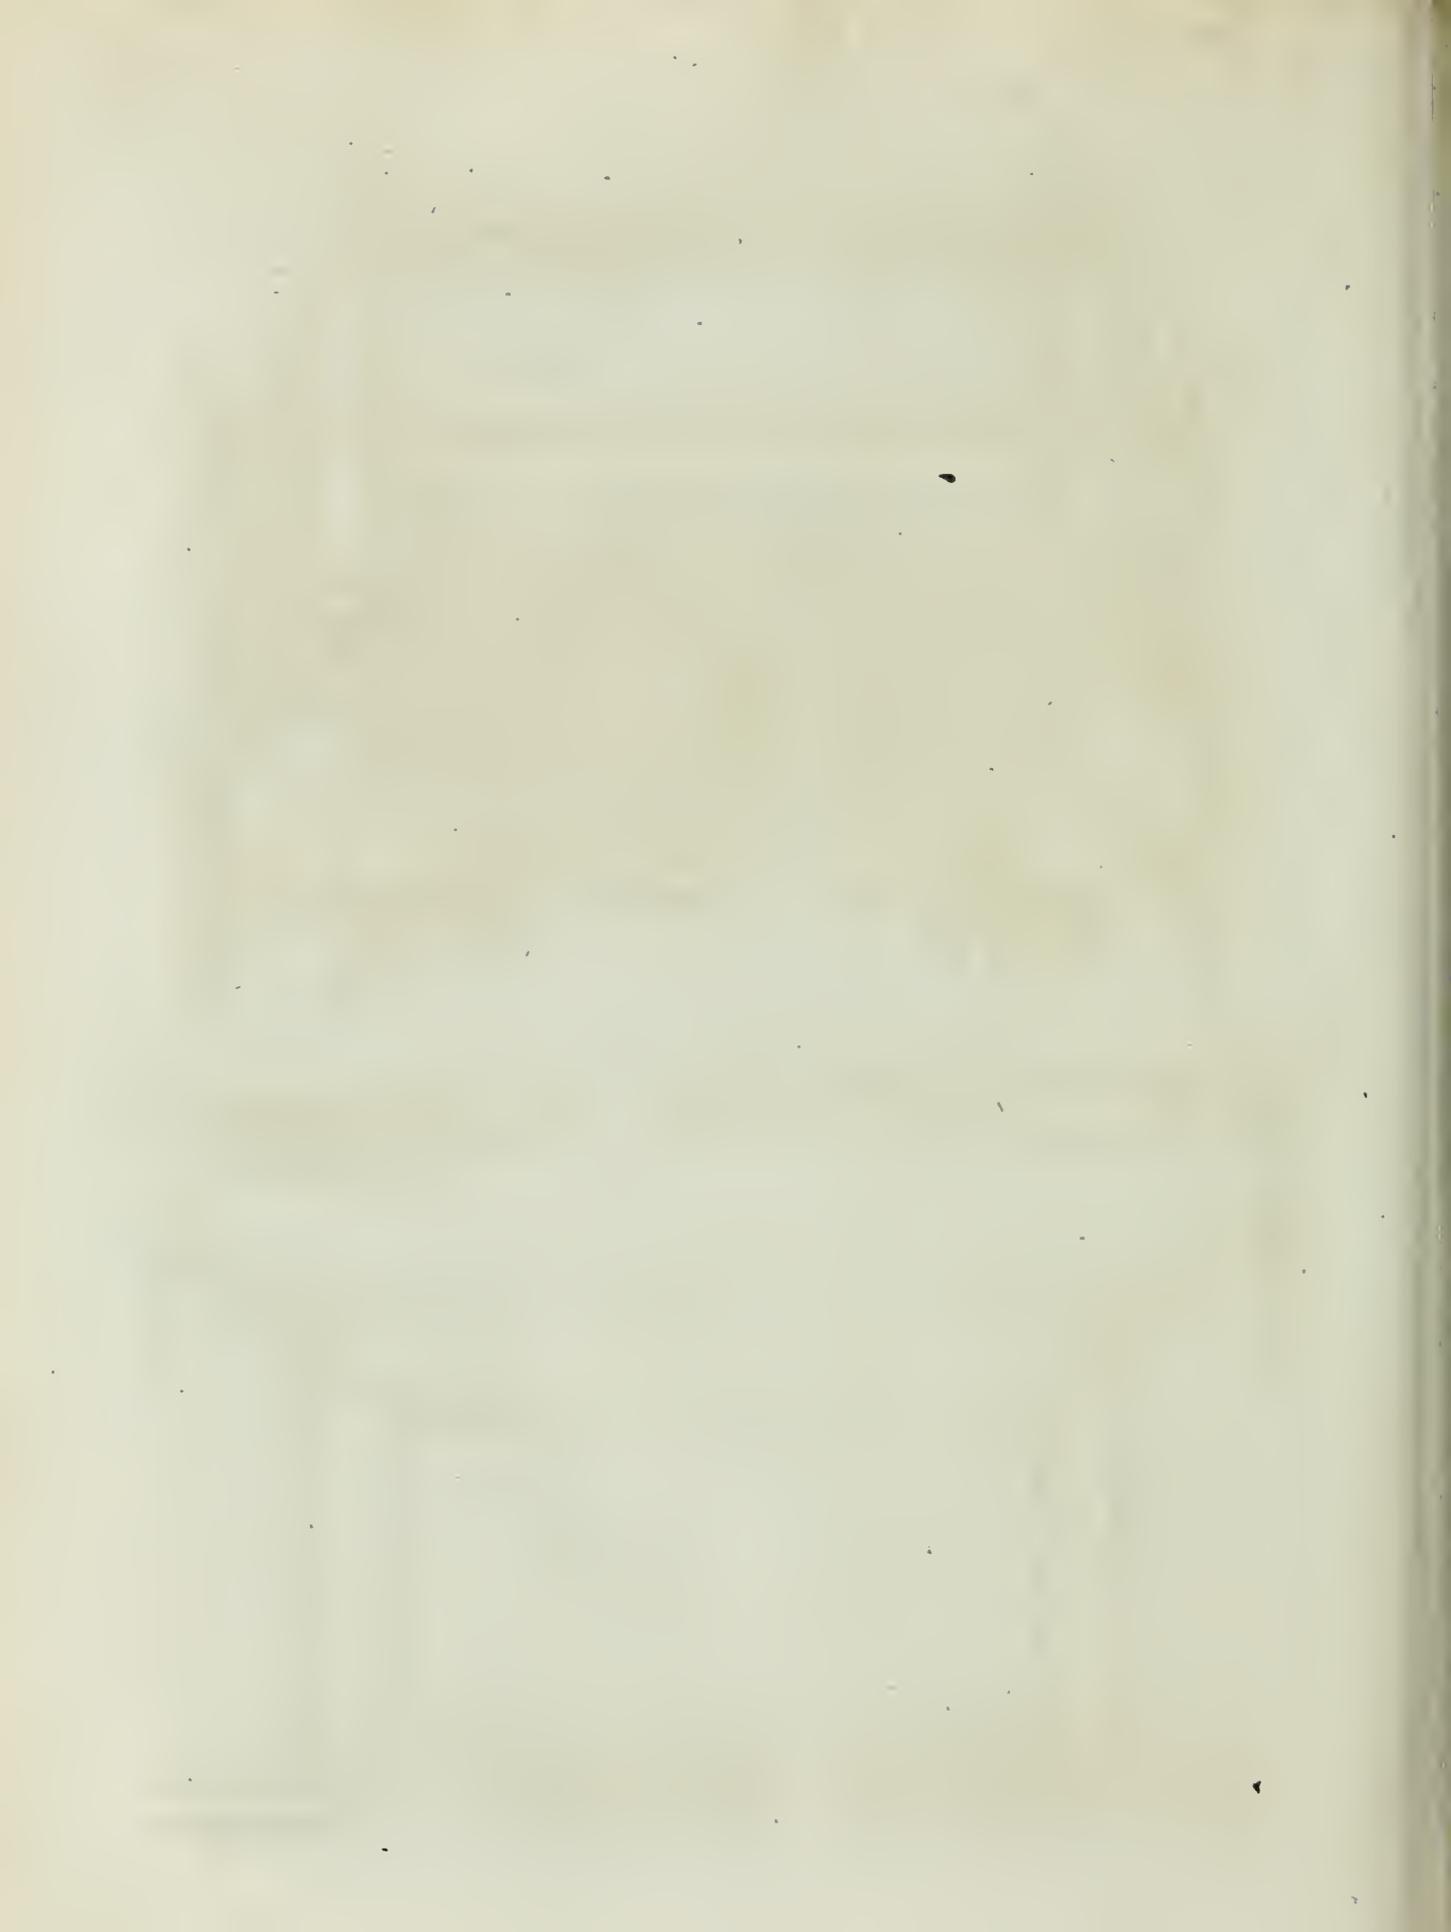

TABLE of Troy Weight, as used by the Goldsmiths, &c. Apothecaries.

Grains.			
24	Penny-weight.		
480	20	Ounce.	
5760	240	12	Pound.
Grains.			
20	Scruple. ʒ		
60	3	Dram. ʒ	
480	24	8	Ounce. ʒ
5760	288	96	12 Pound.

The troy pound in Scotland, which by statute is to be the same as the French pound, is commonly supposed equal to 15 ounces and three quarters troy English weight, or 7560 grains. But by a mean of the standards kept by the dean-of-guild of Edinburgh, it weighs $7599\frac{7}{8}$ or 7600 grains.

TABLE of Avoirdupois Weight.

Drams.				
16	An ounce.			
256	16	A pound.		
7168	448	28	A quarter.	
28672	1792	112	4	A hundred.
573440	35840	2240	80	20 A ton.

The avoirdupois pound is equal to 7004 troy grains, the avoirdupois ounce to 437.75 grains; and it follows of consequence, that the troy pound is to the avoirdupois pound as 88 to 107 nearly; for as 88 to 107, so is 5760 to 7003.636: that the troy ounce is to the avoirdupois ounce as 80 to 73 nearly; for as 80 to 73, so is 480 to 438. An avoirdupois pound is equal to 1 lb. 2 oz. 11 dwts. 20 gr. troy: a troy ounce is equal to 10 z. 1.55 dr. avoirdupois; an avoirdupois dram contain 27.34375 grains; 175 troy pounds are equal to 144 avoirdupois pounds.

The moneyers have a peculiar subdivision of the grain troy: thus,

The $\left\{ \begin{array}{l} \text{Grain} \\ \text{Mite} \\ \text{Droit} \\ \text{Periot} \end{array} \right\}$ into $\left\{ \begin{array}{l} 20 \text{ Mites.} \\ 24 \text{ Droits.} \\ 20 \text{ Periots.} \\ 24 \text{ Blanks.} \end{array} \right.$

The English weights are used in the United Provinces of America.

2. French Weights.—Different weights were formerly used in most of the different provinces of France; we believe that they have lately undergone several alterations; a project of this kind is given in the article REVOLUTION of France. Be that as it may, a knowledge of the ancient weights of that country is of importance on account of the books in which they are used. The Paris pound contains 16 ounces, and is divided two ways.

Grains.				
24	Penny-weight.			
72	3	Gros.		
576	24	8	Ounce.	
4608	192	64	8	Marc.
9216	384	128	16	2 Pound.

Half-ounce.

2	Ounce.			
4	2	Half-quarter pound.		
8	4	2	Quarter-pound.	
16	8	4	2	Half pound.
32	16	8	4	2 Pound.
3200	600	800	400	200 100 Quintal.

Weight.

The weights of the first division are used to weigh gold, silver, and the richer commodities; and the weights of the second division for commodities of less value.

The Paris 2 marc, or pound weight, is equal to 7560 grains troy, and the Paris ounce equal to 472.5 grains troy.

lb. oz. dwt. gr.

The Paris pound = 1 3 15 0 troy

The Paris ounce = 0 0 19 16.5 troy.

A grain troy = 1.2186507 of a Paris grain.

But the pound was not the same throughout France. At Lyons, *e. gr.* the city pound was only 14 ounces: so that 100 Lyons pounds made only 86 Paris pounds. But beside the city pound, they had another at Lyons for silk, containing 15 ounces. At Thoulouse, and throughout the Upper Languedoc, the pound was 13 ounces and a half of Paris weight. At Marseilles, and throughout Provence, the pound was 13½ ounces of Paris weight. At Rouen, beside the common Paris pound and marc, they had the weight of the vicomte; which was 16 ounces, a half, and five-sixths of the Paris weight. The weights enumerated under the two articles of English and French weights are the same that are used throughout the greatest part of Europe; only under somewhat different names, divisions, and proportions.

French weights are used in all the French American settlements.

3. Dutch Weights.—The weight used in Amsterdam and all over Holland is called *Troy weight*, and is exactly the same with that used at Brussels. The Dutch weights are as follows:

Denskens.				
2	Troyken.			
4	2	Vierling.		
16	8	4	As.	
512	256	128	32	Angle.
10240	5120	2560	640	20 Ounce.
3192	4096	20480	512	160 8 Marc.

The marc is equal, according to M. Tillet, to 4620 French grains.

The Amsterdam pound used in commerce is divided into 16 ounces, 32 loots, or 128 drachms. This pound contains 2 marcs troy, and ought therefore to weigh only 10240 *as*: but it weighs 10280; so that it is a little heavier than the troy pound of Amsterdam: 256 lb. of commerce are equal to 257 lb. troy of Holland. Two different pounds are used by apothecaries; the one containing 2 marcs, the other only 1½. The first is called *arsenic* pound weight;

Weight. weight; it contains 16 ounces, the ounce 8 drachms, the drachm 8 scruples, the scruple 20 grains. The second is called the *apothecary's* pound; it is divided into 12 ounces, or 24 loots. Three arsenic pounds are equal to 4 apothecary's pounds.

- The Dutch stone = 8 commercial lb.
- The Lispundt, or Ll. = 15
- The hundred weight = 100
- The Schippontd, or Sch. lb. = 300

4. *Spanish Weights.*—The marc of Castile, used for weighing gold and silver, is divided as follows:

Grains (gold weight).									
12 $\frac{1}{2}$	Grain (silver weight).								
12	11 $\frac{1}{2}$	Tomine (gold weight).							
12 $\frac{1}{2}$	12	1 $\frac{1}{4}$	Tomine (silver weight).						
37 $\frac{1}{2}$	36	3 $\frac{1}{2}$	3	Adarme.					
75	72	6 $\frac{1}{2}$	6	2	Ochava.				
96	92 $\frac{4}{5}$	8	7 $\frac{1}{2}$	2 $\frac{1}{2}$	1 $\frac{1}{2}$	Castellano.			
600	576	50	48	16	8	6 $\frac{1}{4}$	Ounce.		
4800	4608	400	384	128	64	50	8	Marc.	

The marc, according to Tillet, is equal to 7 oz. 4 gros, 8 grains French, which is equal to 4785 *as* of Holland. One hundred marcs of Castile = about 93 $\frac{1}{2}$ marcs of Holland; 100 marcs of Holland = 107 marcs of Castile. Medicines are sold by the same marc; but it is divided differently, containing 8 ounces, 64 drachms, 192 scruples, 384 obolos, 1152 caracteres, 4608 grains.

The Spanish commercial pound is divided into two marcs, called *marcs of Tejo*, each of which is equal to the marc of Castile. This pound is divided into 16 ounces, 256 adarmes, 9,216 grains.

5. *Weights of Portugal.*—The Lisbon marc for assaying silver consists of 12 deniers, and the denier of 24 grains. The marc of Portugal for weighing gold and silver is equal, according to Tillet, to 7 ounces, 3 $\frac{1}{2}$ gros, and 34 grains French, which makes 4776 *as* of Holland; so that it is exactly the same with the Lisbon pound. It is divided into 8 ounces, 64 outavas, 192 scruples, 4608 grains.

The pound consists of 2 marcs, 16 ounces, or 96 outavas. The arroba of 32 lb. the quintal of 4 arrobas, or 128 lb. 100 Oporto pounds make 8 $\frac{1}{2}$ th pounds of commerce of Amsterdam.

6. *Weights of Italy.*—*Genoa.* Two kinds of weights are used at Genoa, the *peso grosso* (heavy weight), and the *peso sottile* (light weight); the latter is used for weighing gold and silver, the former for other things. The pound of the peso sottile is equal, according to Tillet, to 1 marc, 2 ounces, 2 $\frac{1}{2}$ gros, 30 grains French. It is divided into 8 ounces, the ounce into 24 deniers, and the denier into 24 grains. The pound of the peso grosso is equal to 1 marc, 2 ounces, 3 gros, 5 grains, French. It is divided into 12 ounces:

- The cantaro = 100 lbs. peso grosso.
- The rubbo = 25 lbs.
- The rotolo = 1 $\frac{1}{2}$ lb.
- 100 lbs. peso grosso = 6 $\frac{1}{4}$ lb. of commerce of Amsterdam.
- 100 lbs. peso sottile = 129 marcs troy of Holland.

Rome. The Roman pound consists of 12 ounces, the

ounce of 24 deniers, the denier of 24 grains. The Roman pound, according to Tillet, is equal to .x. marc, 3 ounces 5 gros, 14 grains, French.

Venice. The marc for weighing gold and silver contains 8 ounces, 32 quarti, 1152 carati, or 4608 grani. An hundred marcs of Venice = 97 $\frac{1}{2}$ marcs troy of Holland, 100 marcs of Holland = 103 of Venice. In Venice they also use a *peso grosso* and *peso sottile*. 100 lbs. peso grosso = 94 $\frac{2}{3}$ commercial lbs. of Amsterdam. 100 lbs. peso sottile = 61 $\frac{1}{2}$ ditto.

7. *Swedish Weights.*—The marc for weighing gold and silver is equal to 16 lods, 64 quintins, or 4384 *as*. The pound of 32 lods, used for weighing food, is equal, according to Tillet, to 1 marc, 5 ounces, 7 gros, 8 grains French, which makes 8848 $\frac{1}{2}$ *as* troy of Holland. This answers exactly to the weight of the different pounds, as fixed in Sweden, viz. 8848 *as* = the pound for weighing articles of food; 7821 $\frac{2}{3}$ *as* = marc used in the mines; 7450 $\frac{1}{3}$ *as* = marc used in towns and in the country; 7078 $\frac{2}{3}$ *as* = marc used for weighing iron; 7416 *as* = pound used in medicine.

- The skippund = 400 lbs. for weighing food.
- The centner = 120 lbs.
- The waag = 165 lbs.
- The sten = 32 lbs.
- The Swedish *as* = 1 *as* of Holland troy.

8. *German Weights.*—*Vienna.* The marc of Vienna for weighing gold and silver is divided into 16 loths, 64 quintals, or 256 deniers or pfenings; the loth into 4 quintals, or 16 pfenings. This marc, according to Tillet, is equal to 1 marc, 1 ounce, 1 gros, 16 grains, French, = 5831 *as* troy Holland. The pound of Vienna is divided into 2 marcs, or 4 viertings, the mark into 8 ounces, 16 loths, 64 quintals, or 266 pfenings.

Hamburg. The marc for assaying gold is divided into 24 carats; the carat into 12 grains. The marc for silver is divided into 16 loths, and the loth into 18 grains. These marcs consist each of 288 grains, and are therefore equal. This marc, used in Hamburg for gold and silver, is the marc of Cologne, which is equal, according to Tillet, to 7 ounces, 5 gros, 7 $\frac{1}{2}$ grains, French, = 4866 *as* troy of Holland. It is divided into 8 ounces, 16 loths, 64 quintins, 256 pfenings, 4352 eichs; or 65536 richt pfenings theile. The apothecary pound used in Hamburg, and almost all Germany, is divided into 12 ounces, 96 drachms, 288 scruples, or 5760 grains; an ounce is equal to 621 *as* of Holland. The pound of commerce is equal, according to Tillet, to 10085 *as* of Holland; for half a pound is equal to 7 ounces, 7 gros, 23 grains, French. This pound is divided into 16 ounces, 22 loths, 128 quintins, or 512 pfenings.

- 9. *Russian Weights.*—The berckowitz = 400 lbs.
- The poud = 40 lbs.

The pound is divided into 32 loths, or 96 lolotnuks. One hundred Russian lbs. = 166 $\frac{1}{2}$ marcs, or 82 $\frac{1}{2}$ lbs. of Amsterdam. One hundred lbs. of commerce of Amsterdam = 120 $\frac{1}{2}$ th lbs. of Russia.

10. *Weights used in the several parts of Asia, the East Indies, China, Persia, &c.*—In Turkey, at Smyrna, &c. they use the batman, or battemant, containing 7 $\frac{1}{2}$ ocos; the oco contains 4 chekys or pounds, each of which, according to Tillet, is equal to 1 marc 2 oz. 3 gros. 28 gr. French. The Turkish weights are divided as follows:

- Canaras. Batmans. Ocos. R to us. Chekis. Metcal. Drachms.
- 1 = 7 $\frac{1}{2}$ = 44 = 100 = 176 = 11733 $\frac{1}{2}$ = 17609
- 1 = 6 = 13 $\frac{1}{2}$ = 24 = 1600 = 2400
- 1 = 2 $\frac{1}{4}$ = 4 = 266 $\frac{2}{3}$ = 400
- 1 = 1 $\frac{1}{2}$ = 117 $\frac{1}{2}$ = 176
- 1 = 66 $\frac{2}{3}$ = 100
- 1 = 1 $\frac{1}{2}$

At Aleppo there are three sorts of rottes; the first 720 drachms, making about 7 pounds English, and serving to weigh cottons, galls, and other large commodities; the second is 680 drachms, used for all silks but white ones, which are weighed by the third rotto of 700 drachms. At Seyda the rotto is 600 drachms.

The other ports of the Levant not named here, use some of these weights; particularly the occa, or occua, the totoli, and rotto.

The Chinese weights are the piece for large commodities; it is divided into 100 catis, or catts; though some say into 125; the cati into 16 taels, or taels; each tael equivalent to $1\frac{1}{4}$ of an ounce English, or the weight of 1 rial and $\frac{1}{11}$, and containing 12 mas, or masses, and each mas 10 condrius. So that the Chinese piece amounts to 137 pounds English avoirdupois, and the cati to 1 pound 8 ounces. The picol for silk containing 65 catis and $\frac{3}{4}$; the bahar, bakaire, or barr, containing 300 catis.

Tonquin has also the same weights, measures, &c. as China. Japan has only one weight, viz. the cati; which, however, is different from that of China, as containing 20 taels. At Surat, Agra, and throughout the states of the Great Mogul, they use the man, or maund, whereof they have two kinds; the king's man, or king's weight; and the man simply; the first used for the weighing of common provisions, containing 40 seers, or ferres; and each seer a just Paris pound. The common man, used in the weighing of merchandise, consists likewise of 40 seers, but each seer is only estimated at 12 Paris ounces, or $\frac{1}{4}$ of the other seer.

The man may be looked upon as the common weight of the East Indies, though under some difference of name, or rather of pronunciation; it being called *man* at Cambaya, and in other places *mein*, and *moun*. The seer is properly the Indian pound, and of universal use; the like may be said of the bahar, tael, and catti, above mentioned.

The weights of Siam are the piece, containing two shans or catts; but the Siamese catti is only half the Japanese, the latter containing 20 taels, and the former only 10; though some make the Chinese catti only 16 taels, and the Siamese 8. The tael contains 4 baats or ticals, each about a Paris ounce; the baat 4 selings or mayons; the mayon 2 fouangs; the fouang 4 payes; the paye 2 clamis; the sompaye half a fouang.

It is to be observed, that these are the names of their coins as well as weights; silver and gold being commodities there sold, as other things, by their weights.

In the isle of Java, and particularly at Bantam, they use the pantan, which amounts to near 3 Dutch pounds. In Golconda, at Visapour, and Goa, they have the turatelle, containing 1 pound 14 ounces English; the mangalis, or mangelin, for weighing diamonds and precious stones, weighing at Goa 5 grains, at Golconda, &c. $5\frac{1}{2}$ grains. They have also the rotolo, containing $14\frac{1}{4}$ ounces English; the metriol, containing the sixth part of an ounce; the wall for pistres and ducats, containing the 73d part of a rial.

In Persia they use two kinds of batmans or mans; the one called *tahi* or *cheray* which is the king's weight, and the other *batman of Tauris*. The first weighs 13 pounds 10 ounces English; the second $6\frac{1}{4}$ pounds. Its divisions are the ratel, or a 16th; the derhem, or drachm, which is the 50th; the meschal, which is half the derhem; the dung, which is the sixth part of the meschal, being equivalent to 5 carat grains; and, lastly, the grain, which is the fourth part of the dung. They have also the vakie, which exceeds a little our ounce; the sah-cheray, equal to the 1170th part of the derhem; and the toman, used to weigh out large payments of money without telling; its weight is that of 50 *bafts*.

11. *Weights at Cairo in Egypt.*—Almost every kind of goods has its own weight; these are regulated by the cantaren or principal weight.

	Rotels.
The ordinary cantaren, or hundred weight, weighs	100
The cantaren of quicksilver and tin	102
coffee, wine, and iron	105
ivory	100
almonds and other fruits	115
woods for dying	120
arsenic and other drugs	125
minium and cinnabar	130
gum-arabic, aloes, and other aromatics	133

The rotel or rotoli is nearly equal to the pound of Marseilles; 108 lbs. of Marseilles are equal to 110 rotels. The Marseilles pound consists of 13 ounces of Paris; so that 100 lbs. of Marseilles are equal to 81 lbs. Paris, and 100 lbs. Paris = 123 lbs. of Marseilles.

We shall subjoin here Mr Ferguson's table for comparing the English avoirdupois pound with foreign pounds:

London pound	1.0000	Hamburgli	1.0865	<i>Ferguson's Table and Trade.</i>
Antwerp	1.01	Lisbon	1.135	
Amsterdam	1.1111	Leghorn	0.75	
Abeville	1.0989	Norimberg	1.1363	
Ancona	0.78	Naples	0.71	
Avignon	0.8928	Paris	1.1235	
Bourdeaux	1.0989	Prague	1.2013	
Bologna	0.8	Placentia	0.72	
Bruges	1.0204	Rochelle	0.8928	
Calabria	0.73	Rome	0.7574	
Calais	0.9245	Rouen	1.1009	
Dieppe	1.0989	Seville	0.9259

Ferrara	0.75	Turin	0.82	
Flanders	0.9433	Venice	1.06	
Geneva	1.07	Vienna	1.23	
Genoa, gros	0.7			

In order to show the proportion of the several weights used throughout Europe, we shall add a reduction of them to one standard, viz. the London pound.

The 100 lb. of England, Scotland, and Ireland are equal to

lb. oz.	
91	8 of Amsterdam, Paris, &c.
96	8 of Antwerp or Brabant.
88	0 of Rouen, the viscounty weight.
106	0 of Lyons, the city weight.
90	9 of Rochelle.
107	11 of Thouloufe and Upper Languedoc.
113	0 of Marseilles or Provence.
81	7 of Geneva.
93	5 of Hamburgli
89	7 of Francfort, &c.
96	1 of Leipzig, &c.
137	4 of Genoa.
132	11 of Leghorn.
153	11 of Milan.
152	0 of Venice.
154	10 of Naples.
97	0 of Seville, Cadiz, &c.
104	13 of Portugal.
95	5 of Leige.
112	$\frac{2}{3}$ of Ruffin.
107	$\frac{1}{4}$ of Sweden.
89	$\frac{1}{2}$ of Denmark.

A curious weighing machine was some time ago invented by M. Hanin of Paris, whereby the weights of the principal coun-

Weight. countries in Europe, and the relative proportions they bear to each other, are shown at one view. For this he received a bounty of 20 guineas from the Society instituted at London for the Encouragement of Arts, Manufactures, and Commerce. We shall insert a description and figure of this ingenious machine.

Plate Figure 1. represents the back of the machine, which being suspended by the ring A, and a weight hung to the hook B, the spring C, C, C, made fast by strong screws at g, is drawn downwards; and the bar D, having a rack thereon at e, turns the pinion f, in proportion to the weight of the body hanging thereto. Figure 2. shows the face of the machine, on which are a number of concentric circles, and the weights of several countries of Europe engraved thereon, as expressed by the words on a line with them. In the centre of this face is a ring fixed to the small plate, turned by the pinion f, shown at figure 1. From this ring a hand projects, which, by the turning of the pinion, points to such part of the circle as is marked with the weight, hung to the hook B; and thereby shows what weight of any of the countries mentioned, is equal to the pounds troy of London, which are engraved on the outer circle, or to the pounds avoirdupois, which are engraved on the second circle, and so of the rest. A slider moves on the hand, which may be brought to any of the circles at pleasure, in order to point out the relative weight with greater precision.

Many attempts have been made to introduce an uniformity of weights and measures into the commercial world; but hitherto they have all failed. The accomplishment of such an undertaking would be of infinite advantage to mankind, and certainly claims the most serious attention of those who by their situation can alone bring it about. The undertaking is indeed difficult, but surely not impossible. Something of this kind has lately been attempted in France; and if it succeed, as the method is simple, and exceedingly well adapted for calculation, it surely deserves to be imitated. See *REVOLUTION of France*.

WEIGHT of Air. See PNEUMATICS, n^o 14—19.

Regulation of WEIGHTS and MEASURES, is a branch of the king's prerogative. See PREROGATIVE and MEASURE.

As weight and measure are things in their nature arbitrary and uncertain, it is therefore expedient that they be reduced to some fixed rule or standard: which standard it is impossible to fix by any written law or oral proclamation; for no man can, by words only, give another an adequate idea of a foot rule, or a pound weight. It is therefore necessary to have recourse to some visible, palpable, material standard; by forming a comparison with which all weights and measures may be reduced to one uniform size; and the prerogative of fixing this standard, our ancient law vested in the crown, as in Normandy it belonged to the duke. This standard was originally kept at Winchester: and we find in the laws of king Edgar, near a century before the conquest, an injunction that the one measure, which was kept at Winchester, should be observed throughout the realm. Most nations have regulated the standard of measures of length by comparison with the parts of the human body; as the palm, the hand, the span, the foot, the cubit, the ell (*ulna* or arm), the pace, and the fathom. But as these are of different dimensions in men of different proportions, our ancient historians inform us, that a new standard of longitudinal measure was ascertained by king Henry the First; who commanded that the *ulna*, or ancient ell, which answers to the modern yard, should be made of the exact length of his own arm. And one standard of measure of length being gained, all others are easily derived from thence; those of greater length by multiplying, those of less by dividing, that

original standard. Thus, by the statute called *compositio ulnarum et perticarum*, five yards and an half make a perch; and the yard is subdivided into three feet, and each foot into 12 inches; which inches will be each of the length of three grains of barley. Superficial measures are derived by squaring those of length; and measures of capacity by cubing them. The standard of weights was originally taken from corns of wheat, whence the lowest denomination of weights we have is still called a *grain*; 32 of which are directed, by the statute called *compositio mensurarum*, to compose a penny-weight, whereof 20 make an ounce, 12 ounces a pound, and so upwards. And upon these principles the first standards were made; which, being originally so fixed by the crown, their subsequent regulations have been generally made by the king in parliament. Thus, under king Richard I. in his parliament holden at Westminster, A. D. 1197, it was ordained that there should be only one weight and one measure throughout the kingdom, and that the custody of the assize, or standard of weights and measures, should be committed to certain persons in every city and borough; from whence the ancient office of the king's aulnager seems to have been derived, whole duty it was, for a certain fee, to measure all cloths made for sale, till the office was abolished by the statute 11th and 12th William III. c. 20. In king John's time this ordinance of king Richard was frequently dispensed with for money; which occasioned a provision to be made for enforcing it, in the great charters of king John and his son. These original standards were called *pondus regis*, and *mensura domini regis*, and are directed by a variety of subsequent statutes to be kept in the exchequer chamber, by an officer called the *clerk of the market*, except the wine gallon, which is committed to the city of London, and kept in Guildhall.

The *Scottish* standards are distributed among the oldest boroughs. The elwand is kept at Edinburgh, the pint at Stirling, the pound at Lanark, and the silot at Linlithgow.

Various statutes have been enacted for regulating and enforcing an uniformity of weights and measures; and by the articles of union, the English standards are established by law over all Great Britain. But the force of custom is so strong, that these statutes have been ill observed. The Scottish standards are still universally retained for many purposes; and likewise a variety of local weights and measures are used in particular places of both countries, which differ from the general standards of either.

WELD, or WOLD, in botany. See RESEDA.

WELDING-HEAT, in smithery, a degree of heat given to iron, &c. sufficient to make the surfaces of two pieces incorporate upon being beaten together with a hammer.

WANMANNIA, in botany: A genus of plants of the class *obandria*, order *monogynia*, and arranged in the natural classification with those plants the order of which is doubtful. The calyx is four-leaved, the corolla has four petals, and the capsule is bilocular and bistrated. There are four species, none of which are natives of Britain.

WELL, a hole under ground, usually of a cylindrical figure, and walled with stone and mortar: its use is to collect the water of the strata around it.

WELL, an apartment formed in the middle of a ship's hold to inclose the pumps, from the bottom to the lower deck. It is used as a barrier to preserve those machies from being damaged by the friction or compression of the materials contained in the hold, and particularly to prevent the entrance of ballast, &c. by which the tubes would presently be choked, and the pumps rendered incapable of service. By means of this inclosure, the artificers may likewise more readily descend into the hold, in order to examine

amine the state of the pumps, and repair them as occasion requires.

Well-room of a Boat, the place in the bottom where the water lies, between the ceiling and the platform of the Stern-sheets, whence it is thrown out into the sea with a scoop.

Burning-Well. See *BURNING-SPRINGS*.

Well of a Fishing-vessel, an apartment in the middle of the hold, which is entirely detached from the rest, being lined with lead on every side, and having the bottom thereof penetrated with a competent number of small holes, passing also through the ship's floor; so that the salt-water running into the well is always kept as fresh as that in the sea, and yet prevented from communicating itself to the other parts of the hold.

Well-hole, in building, is the hole left in a floor for the stairs to come up through.

WELLS, a city of Somersetshire, and see of a bishop; the bishop of Bath being also that of Wells.—It is supposed to take its name from the many springs and wells that are near it. It is not very large; but is adorned with handsome buildings, both public and private. Its cathedral is a very beautiful structure, adorned with images and carved stone-work. The bishop's palace joins to the cathedral; and on the other side are the houses for the prebendaries. In the market-place is a fine market-house, supported by pillars. It is governed by a mayor, and sends two members to parliament. The chief manufacture is knit hose. W. Long. 2. 37. N. Lat. 51. 12.

WEN, a tumor or excrescence arising on different parts of the body, and containing a cyclus or bag filled with some peculiar kind of matter. See *NEVUS*.

WEREGILD, the price of *homicide*; paid partly to the king for the loss of a subject, partly to the lord whose vassal he was, and partly to the next of kin of the person slain.

WERST, **WURST**, or *Verst*, a Russian measure equal to 3500 English feet. A degree of a great circle of the earth contains about 104 wersts and a half.

WERTURIAN or *URALIAN Mountains*, a famous chain of mountains forming part of the boundary of Asia. It begins distinctly (for it may be traced interruptedly farther south) near the town of Kungur, in the government of Kasan, in latitude 57. 20.; runs north, and ends opposite to the Waygatz strait, and rises again in the isle of *Nova Zemlja*. The Russians also call this range *Semennoi Poias*, or, *the girdle of the world*; from a supposition that it encircled the universe. These were the *Riphsai montes*: *Pars mundi damnata a natura rerum, et densa mersa caligine* &c; of which only the southern part was known to the ancients, and that to little as to give rise to numberless fables. Beyond these were placed the happy *Hyperborei*, a fiction most beautifully related by Pomponius Mela. Moderns have not been behind-hand in exaggerating several circumstances relative to these noted hills. Ysbrand Ides, who crossed them in his embassy to China, asserts that they are 5000 toises or fathoms high; others, that they are covered with eternal snow. The last may be true in their more northern parts; but in the usual passages over them, they are free from it three or four months.

The heights of part of this chain have been taken by M. l'Abbé d'Auteroche; who, with many assurances of his accuracy, says, that the height of the mountain Kyria near Solikamskaia, in latitude 60°, does not exceed 471 toises from the level of the sea, or 286 from the ground on which it stands. But, according to M. Gmelin, the mountain Pauda is much higher, being 752 toises above the sea. From Petersburg to this chain is a vast plain, mixed with

certain elevations or platforms, like islands in the midst of an ocean. The eastern side descends gradually to a great distance into the wooded and mossy Siberia, which forms an immense inclined plane to the Icy Sea. This is evident from all the great rivers taking their rise on that side, some at the amazing distance of latitude 46; and, after a course of above 27 degrees, falling into the Frozen Ocean, in latitude 73. 30. The Yaik alone, which rises near the southern part of the eastern side, takes a southern direction, and drops into the Caspian Sea. The Dwina, the *Peczora*, and a few other rivers in European Russia, show the inclined plane of that part. All of them run to the Northern Sea; but their course is comparatively short. Another inclination directs the Dnieper and the Don into the Euxine, and the vast Wolga into the Caspian Sea.

WESLEY (John), one of the most extraordinary characters that ever existed; whether we consider him as a various and voluminous writer, a zealous and indefatigable preacher, or the founder of the most numerous sect in the Christian world; was the son of the Reverend Samuel Wesley, rector of Epworth in the isle of Axholme in Lincolnshire, and was born in that village in the year 1703. His very infancy was distinguished by an extraordinary incident. The parsonage-house at Epworth was burnt to the ground, and the flames had spread with such rapidity, that few things of value could be saved. His mother, in a letter to her son Samuel Wesley, then on the foundation at Westminster school, thanks God that no lives were lost, although for some time they gave up *Poor Jacky*, as she expresses herself; for his father had twice attempted to rescue the child, but was beaten back by the flames. Finding all his efforts ineffectual, he resigned him to Divine Providence. But parental tenderness prevailed over human fears, and Mr Wesley once more attempted to save his child. By some means equally unexpected and unaccountable, the boy got round to a window in the front of the house, and was taken out, by one man's leaping on the shoulders of another, and thus getting within his reach. Immediately on his rescue from this very perilous situation the roof fell in. This extraordinary escape explains a certain device, in a print of Mr John Wesley, engraved by Vertue, in the year 1745, from a painting by Williams. It represents a house in flames, with this motto from the prophet, "Is he not a brand plucked out of the burning?" Many have supposed this device to be merely emblematical of his spiritual deliverance; but from this circumstance it is apparent that it has a primary as well as a secondary meaning: it is real as well as allusive. This fire happened when Mr Wesley was about six years old.

In the year 1713 he was entered a scholar at the charter-house in London, where he continued seven years under the tuition of the celebrated Dr Walker, and of the Reverend Andrew Tooke author of *The Pantheon*. Being elected to Lincoln college, Oxford, he became a fellow of that college about the year 1725, took the degree of Master of Arts in 1726, and was joint tutor with the Reverend Dr Hutchins the rector. He discovered very early an elegant turn for poetry. Some of his gayer poetical effusions are proofs of a lively fancy and a fine classical taste; and some translations from the Latin poets, while at college, are allowed to have great merit. He had early a strong impression, like Count Zinzendorf, of his designation to some extraordinary work. This impression received additional force from some domestic incidents; all which his active fancy turned to his own account. His wonderful preservation, already noticed, naturally tended to cherish the idea of his being destined by Providence to accomplish some purpose or other, that was out of the ordinary course of human events. The late Reverend

Wesley. Samuel Barcock, in a letter inserted in the *Bibliotheca Topographica Britannica*, N^o XX. says, "There were some strange phenomena perceived at the parsonage at Epworth, and some uncommon noises heard there from time to time, which he was very curious in examining into, and very particular in relating. I have little doubt that he considered himself the chief object of this wonderful visitation, indeed his father's credulity was in some degree affected by it; since he collected all the evidences that tended to confirm the story, arranged them with scrupulous exactness, in a manuscript consisting of several sheets, and which is still in being. I know not what became of the ghost of Epworth; unless, considered as the prelude to the noise Mr John Wesley made on a more ample stage, it ceased to speak when he began to act."

"The dawn of Mr Wesley's public mission (continues Mr Barcock) was clouded with mysticism; that species of it which affects silence and solitude; a certain inexplicable introversion of the mind, which abstracts the passions from all sensible objects; and, as the French Quietists express it, perfects itself by an absorption of the will and intellect, and all the faculties, into the Deity." In this palpable obscure the excellent Fenelon led himself when he forsook the shades of Pindus, to wander in quest of pure love with Madam Guyon! Mr Wesley pursued for a while the same *ignis fatuus* with Mr William Law and the Ghost of De Renty. A state, however, to torpid and ignoble, ill suited the active genius of this singular man. His elastic mind gained strength by compression; thence bursting glorious, he passed (as he himself somewhere says) "the immense chasm, upborne on an eagle's wings."

The reading of the writings of this Mr William Law, the celebrated author of *Christian Perfection*, and of *A Serious Address to the Christian World*, contributed moreover, to lead Mr John Wesley and his brother Charles, with a few of their young fellow-students, into a more than common strictness of religious life. They received the sacrament of the Lord's Supper every week; observed all the fasts of the church; visited the prisons; rose at four in the morning; and refrained from all amusements. From the exact method in which they disposed of every hour, they acquired the appellation of *Methodists*; by which their followers have been ever since distinguished.

But a more particular account of the origin of this sect, we shall give from a celebrated publication. "The Methodists (says the editor of this work) form a very considerable class, principally of the lower people in this country. They sprung up about fifty years ago at Oxford, and were soon divided into two parties; the one under the direction of Mr George Whitefield, and the other under that of two brothers, John and Charles Wesley. These leaders, and, if we except Mr William Law, founders of the Methodists, were educated at Oxford, received episcopal ordination, and always professed themselves advocates for the articles and liturgy of the established church; though they more commonly practised the dissenting mode of worship. But conceiving a design of forming separate communities, superior in sanctity and perfection to all other Christian churches, and impressed to a very considerable degree by a zeal of an extravagant and enthusiastic kind, they became itinerant preachers; and, being excluded from most of our churches, exercised their ministry in private houses, fields, &c. not only in Great Britain and Ireland, but also in America; thus collecting a very considerable number of hearers and proteolytes, both among the members of the established church and the dissenters. The theological system of Mr Whitefield and his followers is Calvinistic; that of Mr Wesley and his disciples Arminian; and the latter maintains the possi-

bility of attaining sinful perfection in the present state. The subordinate teachers of both these classes or Methodists are generally men of no liberal education; and they pretend to derive their ministerial abilities from special communications of the spirit. The Methodists of both parties, like other enthusiasts, make true religion to consist principally in certain affections and inward feelings which it is impossible to explain; but which, when analysed, seem to be mechanical in their spring and operation; and they generally maintain, that Christians will be most likely to succeed in the pursuit of truth, not by the dictates of reason, or the aids of learning, but by laying their minds open to the direction and influence of divine illumination; and their conduct has been directed by impulses."

Our readers will judge for themselves, according to their various modes of education, and to the different lights in which they may respectively view the doctrines of our common Christianity, whether this representation of the origin of the Methodists, and of their distinguishing tenets, be accurate and just.—Not presuming to sit in judgment on the religious opinions of any man, we shall only observe, that an appellation originally given in reproach, has been gloried in ever since by those who have distinguished themselves as the followers either of Mr Whitefield or of Mr Wesley. "After the way called *Methodism*, to worship they the God of their fathers." But the ridicule and contempt which the singularity of their conduct produced, both John and Charles Wesley were well qualified to bear. They were not to be intimidated by danger, actuated by interest, or deterred by disgrace.

The boundaries of this island were soon deemed by Mr Wesley too confined for a zeal which displayed the piety of an apostle; and of an intrepidity to which few missionaries had been superior. In 1735 he embarked for Georgia, one of our colonies, which was at that time in a state of political infancy; and the great object of this voyage was to preach the gospel to the Indian nations in the vicinity of that province. He returned to England in 1737. Of his spiritual labours, both in this country and in America, he himself has given a very copious account, in a series of Journals, oriented at different periods. These journals drew upon our laborious preacher and his coadjutors some severe animadversions from two right reverend prelates; Dr George Lavington bishop of Exeter, and Dr William Warburton bishop of Gloucester. The former published, in three parts, *The Enthusiasm of the Methodists and Papists compared*; the third part of this performance containing a personal charge of immoral conduct. Mr Wesley, in his vindication, published a letter to his Lordship, which produced a reply from the latter.

Bishop Warburton's attack is contained in his celebrated treatise, entitled *The Doctrine of Grace: or, The Office and Operations of the Holy Spirit vindicated from the Insults of Infidelity, and the Abuses of Fanaticism: concluding with some thoughts, humbly offered to the consideration of the Established Clergy, with regard to the Right Method of defending Religion against the Attacks of either Party*; 2 vols, small 8vo, 1762. There is much acute reasoning, and much poignant and sprightly wit, in his *Doctrine of Grace*; but there is too much levity in it for a grave bishop, and too much abuse for a candid Christian. On this occasion, Mr Wesley published a letter to the bishop, in which, with great temper and moderation, as well as with great ingenuity and address, he endeavoured to shelter himself from his Lordship's attacks; not only under the authority of the Holy Scriptures, but of the church itself, as by law established.

On his return from Georgia, Mr Wesley paid a visit to
Count

Count Zinzendorf, the celebrated founder of the sect of Moravians, or Hernhutters, at Hernuth in Upper Lusatia. In the following year he appeared again in England, and with his brother Charles, at the head of the Methodists. He preached his first field-sermon at Bristol, on the 2d of April 1738, from which time his disciples have continued to increase. In 1741, a serious altercation took place between him and Mr Whitfield. In 1744, attempting to preach at an inn at Taunton, he was regularly silenced by the magistrates. Although he chiefly resided for the remainder of his life in the metropolis, he occasionally travelled through every part of Great Britain and Ireland, establishing congregations in each kingdom. In 1750 he married a lady, from whom he was afterwards separated. By this lady, who died in 1781, he had no children.

We have already mentioned Mr Wesley as a very various and voluminous writer. Divinity, both devotional and controversial, biography, history, philosophy, politics, and poetry, were all, at different times, the subjects of his pen; and, whatever opinion may be entertained of his theological sentiments, it is impossible to deny him the merit of having done very extensive good among the lower classes of people. He certainly possessed great abilities, and a fluency which was well accommodated to his hearers, and highly acceptable to them. He had been gradually declining for three years before his death; yet he still rose at four in the morning, and preached, and travelled, and wrote as usual. He preached at Leatherhead, in Surrey, on the Wednesday before that event. On the Friday following, appeared the first symptoms of his approaching dissolution. The four succeeding days he spent in praising God; and he left this scene, in which his labours had been so extensive and so useful, at a quarter before ten in the morning of the 2d of March 1791, in the 88th year of his age. His remains, after lying in a kind of state at his chapel in the city-road, dressed in the sacerdotal robes which he usually wore, and on his head the old clerical cap, a bible in one hand, and a white handkerchief in the other, were, agreeably to his own directions, and after the manner of the interment of the late Mr Whitfield, deposited in the cemetery behind his chapel, on the morning of the 9th March, amid an innumerable concourse of his friends and admirers; many of whom appeared in deep mourning on the occasion. One singularity was observable in the funeral service. Instead of, "We give thee hearty thanks, for that it hath pleased thee to deliver this our brother;" it was read "our father." A sermon, previously to the funeral, had been preached by Dr Thomas Whitehead, one of the physicians to the London hospital; and on the 13th the different chapels of his persuasion in London were hung with black.

It has been justly observed of Mr Wesley, that his labours were principally devoted to those who had no instructor; to the highways and hedges; to the miners in Cornwall, and the coaliers in Kingwood. These unhappy creatures married and buried among themselves, and often committed murders with impunity, before the Methodists sprung up. By the humane and active endeavours of Mr Wesley and his brother Charles, a sense of decency, morals, and religion, was introduced into the lowest classes of mankind; the ignorant were instructed, the wretched relieved, and the abandoned reclaimed. His personal influence was greater, perhaps, than that of any other private gentleman in any country.—But the limits of this article will not permit us to expatiate further on the character of this extraordinary man.

WEST (Gilbert), was the son of Dr West, prebendary of Winchester, and chaplain to king George I. but at 12 years of age lost his father. He studied at Winchester and

Eton schools, and from thence was placed in Christ-church college, Oxford. His studious and serious turn inclined him to take orders; but lord Cobham, his uncle, diverted him from that pursuit, and gave him a cornetcy in his own regiment. This profession he soon quitted, on account of an opening of another nature, which presented him with a flattering prospect of advancement in life. A number of young gentlemen were to be elected from the universities, and, at the expence of the government, were to be taught foreign languages; and then sent to the secretaries office; to be initiated into business, and trained there for public services, as envoys, ambassadors, &c. Mr Gilbert West was one of the few pitched upon; and on his first introduction into that office, lord Townsend, secretary of state, treated him with singular marks of regard, and the strongest inclinations to serve him were testified from all quarters. But his uncle lord Cobham's strong opposition to the measures of the government, rendered these advantages entirely fruitless; and the ministers honestly told Mr West, that he must not expect them to distinguish his merit, as any favours conferred upon him would be imputed as done to his uncle lord Cobham. Mr West now left that office, and all his views of making his fortune; and entering into marriage, retired to Wickham in Kent, where he lived in great domestic comfort and tranquil happiness. He was there visited by his valuable friends, who held the most delightful converse of wit, humour, and learning, supported upon the principles of virtue, sound reasoning, and solid friendship, which rendered the whole cheertul, animating, and instructive. Mr William Pitt, who was one of those that composed this happy society, becoming paymaster, appointed Mr West treasurer to Chelsea-hospital; and he obtained a seat at the council board, in consequence of a friendship contracted at school with one of the duke of Devonshire's sons, who procured of his grace his being nominated one of the clerks extraordinary of that office. Towards the latter part of Mr West's life, he wholly applied himself to the study of the Scriptures; being extremely anxious to try his utmost endeavours to reconcile the seeming inconsistencies which gave the enemies to revealed religion a handle to doubt and discredit their authenticity. His observations on the resurrection, which, it has been said, were written to confirm the wavering faith of his great friends Pitt and Lyttleton, bear ample testimony to his reasoning powers and the sincerity of his religion; while his translations of Pindar show him to have been an eminent Greek scholar, and very considerable poet. He had a mind replete with virtue, and was an honour to his country; but died at 50 years of age.

WEST, one of the cardinal points of the horizon, diametrically opposite to the east; and strictly defined the intersection of the prime vertical with the horizon on that side the sun sets in.

WESTMINSTER, a city which forms the west part of the capital of Britain, but has a government distinct from the rest. This city had its name from the situation of its abbey, anciently called a *minster*, in respect of that of St Paul. That part properly called the city of Westminster, comprehending the parishes of St John and St Margaret, was once an island formed by the Thames, called *Thorney island*, from the thorns with which it was over run; and the abbey that stood in it, Thorney-abbey. The liberties of Westminster contain the several parishes of St Martin in the Fields, St James's, St Anne, St Paul, Covent-garden, St Mary le Strand, St Clement, Danes, St George, Hanover Square, and the precinct of the Savoy. The government, both of the city and liberties, is under the jurisdiction of the dean and chapter of Westminster, in civil as well as ecclesiastical affairs; and their authority extends

West.
Westminster.

Westmoreland, Westphalia

to the precinct of St Martin le Grand, by Newgate-street, and in some towns of Essex, thist are exempted from the jurisdiction of the bishop of London and the archbishop of Canterbury; but the management of the civil part has, ever since the Reformation, been in the hands of laymen, elected from time to time, and confirmed by the dean and chapter. The chief of these laymen are the high-steward, the deputy-steward, and the high-bailiff, who hold their offices for life. There are also 16 burgeses and their assistants, out of which are elected two head-burgeses, one for the city, and the other for the liberties. Another officer is the high constable, who has all the other constables under his direction.

WESTMORELAND, a county of England, bounded on the north and north-west by Cumberland; on the south and south-east by Yorkshire; and on the south and south-west by Lancashire. Its extent from north east to south, is 40 miles, and its breadth from the east projection to that in the west, 42. It is generally divided into the baronies of Kendal and Westmoreland: the former is very mountainous, but the latter is a large champaign country. These are the only principal divisions of this county, which contains 8 market towns and 26 parishes. It lies partly in the diocese of Chester, and partly in that of Carlisle. The earl of Thanet is hereditary sheriff of the county, which sends only four members to parliament. The air is clear, sharp, and salubrious, the natives being seldom troubled with diseases, and generally living to old age. The soil is various; that on the mountains is very barren, while that in the valleys is fertile, producing good corn and grass, especially in the meadows near the rivers. In the hilly parts on the western borders it is generally believed there are vast quantities of copper ore, and veins of gold; some mines of copper are worked, but most of the ore lies so deep that it will not answer the expence. This county yields the finest slate, and abundance of excellent hams are cured here. The principal rivers are, the Eden, the Lune, and the Ken. It has also several fine lakes, the principal of which is Windermere, or Windermere Water. In the forest of Martindale, to the south of Ulls-water, the breed of red deer still exists in a wild state.—Appleby is the county town.

WESTPHALIA, a duchy of Germany, bounded to the east by the bishopric of Paderborn, and the territories of Waldeck and Hesse; to the south by the counties of Witgenstein and Nassau, and the duchy of Berg; to the north by the bishopric of Munster and the county of Lippe. It is about 40 miles in length and 30 in breadth. The lower part of it is very fruitful, yielding plenty of corn and cattle, and some salt-springs. The higher affords iron ore, calamine, lead, copper, some silver and gold, fine woods, cattle, game, fish, with a little corn. The rivers, that either pass through the duchy or along its borders, are the Rahr, the Lenne, the Biège, the Dimel, and the Liope. There are 28 towns in it, besides boroughs and cloisters. The provincial diets are held at Arensburg. In the year 1180, the emperor Fred. I. made a donation of this duchy to the archbishopric of Cologne, which was confirmed by succeeding emperors; and in 1638, the last duke of Arensburg ceded to it also the county of Arensburg. The duchy is governed at present by a bailiff, under the archbishop, and is divided into the Hellwege, the Haarfrank, and the Surland; or otherwise into the Ruden, the Werl, the Bilstein, and the Brilon quarters.

WESTPHALIA, one of the circles of Germany, anciently the people inhabiting between the Weser and the Rhine, were called *Westphalians*; and hence that tract got the name of *Westphalia*: but the circle of that name is of a larger extent, being surrounded by the circle of Burgundy, or the

Austrian Netherlands, the United Provinces, and the North Sea, with the circles of the Upper and Lower Rhine, and comprising a great many different states.

The summoning princes and directors of the circle of Westphalia, are the bishops of Munster, alternately with the electors of Brandenburg and Palatine, as dukes of Cleve and Juliers. The archives belonging to it were before the present war (1797) kept at Dusseldorp. Its quota of men and money is somewhat more than the ninth part of the whole sum granted by the empire. With respect to religion, it is partly Protestant and partly Catholic; but the Protestants predominate, and are, at least the greater part of them, Calvinists. The air of this country is not reckoned very wholesome, and towards the north is extremely cold in winter. The soil in general is marshy and barren; yet there is some good corn and pasture land: but the fruit is chiefly used to feed hogs; and hence it is that their bacon and hams are so much valued and admired.

WEL' COUCH, *cominz heap*, a term used by the maltsters for one of the principal articles of malt-making. See BREWING, n^o 4.

WESTSTEIN (John James), a very learned German divine, born at Basil in 1693. On his admission to the ministry, he maintained a thesis *De variis Novi Testamenti Lectionibus*; in which he showed that the great variety of readings of the New Testament afford no argument a gainst the authenticity of the text. He had made these various readings the object of his attention; and travelled into foreign countries to examine all the MSS. he could come at. In 1730, he published *Prolegomena ad Novi Testamenti Græci editionem accuratissimam, &c.* Some divines, dreading his unsettling the present text, procured a decree of the senate of Basil against his undertaking, and even got him prohibited from officiating in the ministry; on which he went to Amsterdam, where the Remonstrants named him to succeed the famous Le Clerc, then superannuated, as professor of philosophy and history. At last he published his edition of the New Testament, in 2 vols folio, 1752; in which he left the text as he found it, placing the various readings, with a critical commentary, underneath; subjoining two epistles of Clemens Romanus, till then unknown to the learned, but discovered by him in a Syriac MS. of the New Testament. He also published some small works; and is said to have been not only an universal scholar, but to have abounded in good and amiable qualities. He died at Amsterdam in 1754.

WELTERAVIA, the southern division of the Landgravate of Hesse in Germany, lying along the northern bank of the river Maine, comprehending the counties of Hanau and Nassau.

WEXFORD, a county of Ireland, in the province of Munster, 38 miles in length, and 24 in breadth; bounded on the north by Wicklow, on the east by St George's Channel, on the south by the Atlantic Ocean, on the west by Waterford and Kilkenny, and on the north by Catherlough. It contains 109 parishes, and sends 18 members to parliament. It is a fruitful country in corn and grass; and the principal town is of the same name.

WEXFORD, a sea-port of Ireland, capital of a county of the same name. It was once reckoned the chief city in Ireland, being the first colony of the English, and is still a large handsome town, with a very commodious harbour at the mouth of the river Slana, on a bay of St George's Channel, 63 miles south of Dublin. W. Long. 6. 3. N. Lat. 52. 18.

WHALE, in ichthyology. See BALÆNA and PHYSETER.

WHALE, in astronomy, one of the constellations. See ASTRONOMY, n^o 406.

Whale-Bone. See *BALÆNA*, n° 2.

Whale-Fishery. See *FISHERY*.

WHARF, a space on the banks of a haven, creek, or hithe, provided for the convenient loading and unloading of vessels.

WHARTON (Philip duke of), a nobleman of the most brilliant parts, but of the most whimsical, extravagant, and inconsistent turn of mind, was educated by his father's express order at home. He very early married a young lady, the daughter of major-general Holmes, which disappointed his father's views of disposing of him in such a marriage as would have been a considerable addition to the fortune and grandeur of his illustrious family; yet that amiable lady deserved infinitely more felicity than she met with by this alliance. This precipitate marriage is thought to have hastened the death of his father; after which the duke, being free from paternal restraints, plunged into those excesses which rendered him, as Pope expresses it,

“ A tyrant to the wife his heart approv'd ;
“ A rebel to the very king he lov'd.”

In the beginning of the year 1716, he began his travels; and as he was designed to be instructed in the strictest Whig principles, Geneva was thought a proper place for his residence. He first passed through Holland, and visited several courts of Germany; and being arrived at Geneva, conceived such a disgust against his governor, that he left him, and set out post for Lyons, where he wrote a letter to the chevalier de St George, who then resided at Avignon, and presented him a very fine stout horse; which the chevalier no sooner received than he sent a man of quality to him, who took him privately to his court, where he was entertained with the greatest marks of esteem, and had the title of duke of Northumberland conferred upon him. He, however, remained there but one day, and then returned post to Lyons, whence he set out for Paris. He likewise paid a visit to the consort of James II. who then resided at St Germain's, to whom he also paid his court. During his stay at Paris, his winning address and abilities gained him the esteem and admiration of all the British subjects of rank of both parties.

About the latter end of December 1716, he arrived in England, whence he soon after set out for Ireland, where, though under age, he was allowed the honour to take his seat in the house of peers, and immediately distinguished himself, notwithstanding his former conduct, as a violent partisan for the ministry; in consequence of which zeal the king created him a duke. He no sooner came of age than he was introduced to the house of lords in England with the same blaze of reputation. In a little time he opposed the court, and appeared one of the most vigorous in defence of the bishop of Rochester; and soon after printed his thoughts twice a-week, in a paper called the *True Briton*, several thousands of which were dispersed weekly.

The duke's boundless profusion had by this time so burdened his estate, that by a decree of Chancery it was vested in the hands of trustees for the payment of his debts, allowing him a provision of L. 1200 *per annum* for his subsistence. This being not sufficient to support his title with suitable dignity, he went abroad and shone to great advantage, with respect to his personal character, at the imperial court. From thence he made a tour to Spain: the English minister was alarmed at his arrival, fearing that his grace was received in the character of an ambassador: upon which the duke received a summons under the privy-seal to return home; but instead of obeying it, he endeavoured to inflame the Spanish court against that of Great Britain, for exercising an act of power, as he calls it, within the jurisdiction

of his Catholic majesty. He then acted openly in the service of the Pretender, and was received at his court with the greatest marks of favour.

Wharton.

While his grace was thus employed, his neglected duchess died in England on the 14th of April 1726, without issue. Soon after the duke fell violently in love with M. Oberne, one of the maids of honour to the queen of Spain, the daughter of an Irish colonel, whose fortune chiefly consisted in her personal accomplishments. All his friends, and particularly the queen of Spain, opposed the match; but he falling into a lingering fever, occasioned by his disappointment, the queen gave her consent, and they were soon after married. He then spent some time at Rome, where he accepted of a blue garter, assumed the title of duke of Northumberland, and for a while enjoyed the confidence of the exiled prince. But not always keeping within the bounds of Italian gravity, it became necessary for him to remove from hence; when, going by sea to Barcelona, he wrote a letter to the king of Spain, acquainting him that he would assist at the siege of Gibraltar as a volunteer. Soon after he wrote to the chevalier de St George, expressing a desire to visit his court; but the chevalier advised him to draw near to England.

The duke seemed resolved to follow his advice; and setting out with his duchess, arrived in Paris in May 1728, whence he soon after proceeded to Rouen, where he took up his residence; and was so far from making any confession to the government of England, that he did not give himself the least trouble about his estate, or any other concern there; though, on his arrival at Rouen, he had only about L. 600 in his possession, and a bill of indictment was preferred against him in England for high-treason. Soon after the chevalier sent him L. 2000, which he squandered away in a course of extravagance; when, to save the charges of travelling by land, he went from Orleans to Nantz by water, and staid there till he got a remittance from Paris, which was squandered almost as soon as received. At Nantz he was joined by his ragged servants, and from hence took shipping with them for Bilbao, when the queen of Spain took the duchess to attend her person. About the beginning of the year 1731, the duke, who commanded a regiment, was at Lerida, but declined so fast that he could not move without assistance; yet when free from pain did not lose his gaiety. He, however, received benefit from some mineral waters in Catalonia; but soon after relapsed at a small village, where he was utterly destitute of all the necessaries of life, till some charitable fathers of a Bernardine convent removed him to their house, and gave him all the relief in their power. Under their hospitable roof he languished a week, and then died, without one friend or acquaintance to close his eyes; and his funeral was performed in the same manner in which the fathers inter those of their own fraternity.

Thus died Philip duke of Wharton. “ who, like Buckingham and Rochester (says Mr Walpole), comforted all the grave and dull, by throwing away the brightest profusion of parts on witty fooleries, debaucheries, and serapes, which mix graces with a great character, but never can compose one.

“ With attachment to no party, though with talents to govern any party, this lively man changed the free air of Westminster for the gloom of the Eucennial, the prospect of king George's garter for the Pretender's; and with indifference to all religion, the frolic lord who had writ the ballad on the archbishop of Canterbury, died in the habit of a capuchin. It is difficult to give an account of the works of a man whose library was a tavern, and women of pleasure his muses. A thousand follies of his imagination may have been lost. There are only two volumes in 8vo,

called

Wheat.

called *his Life and Writings*. These contain nothing of the latter, but 74 numbers of the *True Briton*, and his speech in defence of the bishop of Rochester. His other works are the ballads above mentioned; the *Drinking Match*, at Eden-hall, in imitation of the *Chevy-Chace*, printed in a miscellany called *Whartoniana*; and a parody of a song sung at the opera-house by Mrs Tofts. His lordship also began a play on the story of the queen of Scots."

WHEAT, in botany. See **TRITICUM**. For the culture of wheat, see **AGRICULTURE**, n^o 122—136.

The three principal kinds of bad wheat are, the *blighted*, the *smutty*, and the *worm-eaten*. Blighted wheat is that of which the stalk is a little twisted and rickety, the blade being of a bluish green and curled up, the grain also is green and tubercled: smutty wheat appears as if great part of the ear had been burnt, some small parts only being free, and, in particular, the stem that rises in the centre of the ear, round which the grain is ranged: worm eaten or rotten wheat is corrupted without losing much of its natural form, or external appearance; the husk is filled with a greasy, black powder, that is insufferably fetid. It appeared, from the experiments of M. Tillet, that there was a kind of infectious quality in all those kinds of wheat; so that if sound wheat was sprinkled with the flour of smutty or rotten wheat, the crop produced would be rotten or smutty. It appeared also, that among the grain which was produced from ground manured with the straw of dis-tempered wheat, there was a much greater proportion of dis-tempered wheat than in that produced from ground manured with the straw of good wheat: the great secret then was to destroy the principle of this contagion in the wheat that was put into the ground; and M. Tillet found, as the result of a great number of experiments, that if the grain, before it is sowed, be well moistened with a solution of sea-salt, or nitre, in common water, none of the ensuing crop will be smutty, or otherwise defective, either in kind or quality; not only supposing the grain that is sowed to be found, and the soil to be good, but even supposing the grain to be strewed with the flour of smutty wheat, and the ground manured with bad straw.

The following receipt for preventing smutty wheat was published in 1769 by order of the Society for the Encouragement of Arts: they received it from Mr John Reynolds of Adisham in Kent.

A tub is to be procured that has a hole at bottom, in which a staff and tap-hose is to be fixed over a whisp of straw, to prevent any small pieces of lime passing (as in the brewing way); this done, we put 70 gallons of water, then a corn bushel heap-full of stone-lime, unslaked, stirring it well till the whole is dissolved or mixed, letting it stand about 30 hours, and then run it off into another tub as clear as we can (as practised in beer): this generally produces a hoghead of good strong lime-water; then add three pecks of salt, 42 pounds, which, with a little stirring, will soon dissolve; thus we have a proper pickle for the purpose of brining and liming our seed-wheat without any manner of obstacle, which is more than can be said in doing it the common way, and greatly facilitates the drilling.

Herein we steep the wheat in a broad-bottomed basket of about 24 inches diameter, and 20 inches deep (for large sowing, made on purpose), running in the grain gradually in small quantities from 10 to 12 gallons up to 16 gallons, stirring the same. What floats, we skim off with a strainer, and is not to be sown: then draw up the basket, to drain over the pickle, for a few minutes; all which may be performed within half an hour, sufficiently pickled; and so proceed as before. This done, the wheat will be fit for sowing in 24 hours, if required; but if designed for drill-

ing, two hours pickled will be found best; and if prepared four or five days before-hand, in either case it makes no difference at all; but should the seed be clammy, and stick to the notches in the drill-box, more lime must be added to the lime-water; here the master must use his discretion, as the case requires; for some lime has much more drying or astringent qualities in it than others. If sea-water can be obtained conveniently, much less salt will suffice, but some will be found necessary even then, otherwise the light grains will not float, a thing of more consequence than is generally imagined, and it ought to be skimmed off and thrown aside for poultry, &c.

WHEEL, in mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on its axis. See **MECHANICS**.

WHEEL-Carriages. See **MECHANICS**, Sect. iv.

WHEEL-Animal. See **ANIMALCULE**, n^o 16—23.

WHEEL, Persian. See **HYDROSTATICS**.

WHEEL, Potter's. See **POTTERY**.

WHEEL is also the name of a kind of punishment to which great criminals are put in divers countries. In some, assassins, parricides, and robbers on the highway, are said to be condemned to the wheel, when they are to have their bones first broken with an iron bar on a scaffold, and then to be expoled, and left to expire on the circumference of a wheel. In Germany they break their bones on the wheel itself.—Of this cruel punishment, it is not certain who was the inventor: it was first used in Germany, and was, indeed, but rarely practised anywhere else, till the time of Francis I. of France; who, by an edict of the year 1534, appointed it to be inflicted on robbers on the highway.

WHEELER (Sir George), a learned traveller and divine, was the son of colonel Wheeler of Charing in Kent, and was born in 1650 at Breda, where his parents as royalists were then in exile. He travelled through various parts of Greece and the East in company with Dr James Spon of Lyons; and taking orders on his return, was installed a prebend of Durham, made vicar of Basingstoke, and afterward rector of Houghton le Spring. He published an account of his Travels in 1682 in folio; and in 1689, his Observations on ancient edifices of Churches yet remaining in the East, compared with Eusebius; also the Protestant Monastery, or Christian Economics. He died in 1724.

WHEELINGS, in the military art, are different motions made both by horse and foot, either to the right and left, or to the right and left about.

General Rules for WHEELING.—The circle is divided into four equal points; thence, wheeling to the right or left, is only a quarter of the circle; wheeling to the right or left about is one half of the circle.

When you wheel to the right, you are to close to the right, so near as to touch your right-hand man, but without pressing him; and to look to the left, in order to bring the rank about even.

When you wheel to the left, you are to close to the left, and look to the right as above directed. This rule will serve for all the wheeling by ranks; as when a battalion is marching by subdivisions with their ranks open, then each rank wheels distinctly by itself, when it comes to the ground on which the ranks before it wheeled, but not before.

In wheeling, the men are to take particular care neither to open nor close their ranks, and to carry their arms well.

In wheeling, the motion of each man is quicker or slower, according to the distance he is from the right or the left: thus, when you wheel to the right, each man moves quicker than his right-hand man; and wheeling to the left, each man moves quicker than his left-hand man; the circle that every man wheels being larger, according to the distance he

Prize Dis-
sertation by
the Acad-
emy of Bour-
deaux.

W. 1

Wh. 100

is from the hand he wheels to; as may be seen by describing several circles within one another, at two feet distance from each, which is nearly the space every man is supposed to take up.

WHELK, in zoology. See BUCCINUM.

WHELP, the young of a dog, fox, lion, or any wild beast.

WHELPS, in a ship, the seaman's term for those brackets which are set up on the capstan close under the bars; they give the sweep to it, and are so contrived that the cable winding about them may not surge so much as it might otherwise do it the body of the capstan were quite round and smooth.

WHETSTONE, a stone which serves for the whetting of knives and other tools upon.

WHEY, the serum or watery part of milk.

WHIDAH, a kingdom of Africa, on the coast of Guinea, and to the west of the Gold Coast; extending about 10 miles along the sea. It is a populous country, well furnished with large villages; and there are so many small ones, that they are not above a musket-shot from each other. — The houses are small, round at the top, and encompassed with mud walls or hedges, together with a great number of all sorts of beautiful and lofty trees, which afford the most beautiful prospect in the world, inasmuch that those that have been here represent it as a perfect paradise. The fields are always green, and they cultivate beans, potatoes, and fruits; nor will the negroes here let a foot of ground remain uncultivated. They sow again the very next day after they have reaped. The inhabitants are greatly civilized, very respectful to each other, especially to their superiors, and very industrious. The women brew the beer, dress the victuals, and sell all sorts of commodities at the market. Those that are rich employ their wives and slaves in tilling the land, and they carry on a considerable trade with the product, as well as in slaves; for some of them are able to deliver 1000 of the latter every month. The chief men have generally 40 or 50 wives, the principal captains 300 or 400, and the king 4000 or 5000. They are extremely jealous, and, on the least suspicion, will sell them to the Europeans for slaves. If any one happen to touch one of the king's wives accidentally, he is doomed to perpetual slavery. It is no wonder then that the women are not fond of being the king's wives; and some of them will prefer a speedy death to such a miserable life. They have no distinction of hours, days, weeks, months, or years. The rite of circumcision is used here, but they are not able to tell why they use it, nor whence it is derived. They are such great gamesters, that they will stake all they have at play, not excepting their wives and children. They have a vast number of idols; and they deity the most contemptible animal that they see first in a morning, and even sticks and stones. Their principal regard is for snakes, very high trees, and the sea. An English factor, just arrived, found a snake in the house belonging to the factory, and killed it without the least scruple; which so incensed the negroes, that they were for revenging the death of the snake, not only upon him that killed it, but upon the whole factory; but by dint of presents, and the interposition of the people of the other factories, this affair was made up, and the snake honourably interred. However, to prevent such accidents, they gave them warning not to do the like for the future. They have oxen, cows, goats, sheep, hogs, turkeys, ducks, and hens; which last are extremely plentiful. There are many elephants, buffaloes, tigers, several kinds of deer, and a sort of hares. The fruits are citrons, lemons, oranges, bananas, tamarinds, &c. and they have vast numbers of palm-trees, from which they obtain wine. Whidah was

conquered by the king of Dahomy. Their trade consists of slaves, elephants teeth, wax, and honey. The English factory is 200 miles east of Cape Coast Castle, within land. Bows, arrows, beautiful ash, javays, and clubs, are the principal weapons of the nation.

Whidah
||
Whidah
-wi d.

WHIDAW-BIRD. See EMBERIZA.

WHIGS, a party in Britain, opposite to the Tories, from whom they differ chiefly in their political principles. See TORIES.

WHIMBREL. See SCALOPAX.

WHIN, in botany. See ULEX.

WHINCHET. See MOPACHIA.

WHIP, or *Whip-stick*, in a ship, a piece of timber, in form of a square staff, fastened into the beam, for the steerman, in small ships, to hold in his hand, in order to move the rudder, and direct the ship.

WHIRLPOOL, an eddy, vortex, or gulf; where the water is continually turning round.

Those in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine whirlpool among the Orcaes, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea among these islands. Wherever it appears, it is very furious; and boats, &c. would inevitably be drawn in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing, in the boat with them; as soon as they perceive the whirlpool, they toss this within its vortex, keeping themselves out: this substance, whatever it be, is immediately received into the centre, and carried under water; and as soon as this is done, the surface of the place where the whirlpool was becomes smooth, and they row over it with safety: and in about an hour they see the vortex begin again in some other place, usually at about a mile's distance from the first.

WHIRLWIND, a wind which moves in a spiral direction, as well as horizontally, which is exceedingly rapid and impetuous, but only of short duration.

Dr Franklin's opinion of the origin of whirlwinds has been already given in the article *WATER SPOUT*. If his theory be true, it will follow, that no hurricane ever can be so violent as to remove an obstacle of the size of only one cubic inch, provided that was supported by a power equivalent to 15 pounds; for this is the utmost force of the atmosphere when rushing into a perfect vacuum, which never could take place in the centre of a whirlwind or water-spout. Indeed, notwithstanding the dreadful effects sometimes observed from hurricanes and whirlwinds, we shall easily perceive, that the utmost of their power always falls very far short of this. The diminution of the specific gravity of the air by only $\frac{1}{4}$ th in the middle of the column, would produce such an afflux of air from all quarters, that an obstacle presenting a surface of one foot square, would require a force of 504 pounds to prevent it from being carried away; which the strongest walls that can be built by human art could scarce resist. Nay, even the tenth part of this, or the diminution of the gravity of the atmosphere by $\frac{1}{10}$ th part, would produce a pressure of upwards of 50 pounds on every square foot of surface, which, it is to be doubted, whether any of our common houses could resist.

Some philosophers ascribe the vacuum in the atmosphere to which, according to Dr Franklin's theory, whirlwinds are owing, to a stream of electric matter rushing with violence into the atmosphere out of the earth. But they do not in-

form

Whirl-
wind
||
Whist

form us how this matter comes to be accumulated in that part of the earth; what induces it to pass out of the earth; how it passes invisibly through pure air; or what serves it for a conductor. It seems to be the fashion among certain philosophers to ascribe every phenomenon, with the cause of which we are unacquainted, to electricity. But this is merely substituting a new name, and serves rather to retard than advance our knowledge of nature.

Some kinds of whirlwinds move with a slow motion, and are injurious only by their vortex; while others seem to do mischief as well by their progressive as their whirling motion. Of this kind are those called *typhons*; which, by their frequently following the course of rivers, seem thus also to discover their electrical origin. Of the destructive effects of these, we have an instance in what happened at Charlestown in South Carolina, on the 1st of June 1761. It was first observed about noon, on land, upwards of 50 miles west-by-south of Charlestown, and destroyed several houses, &c. as it passed along, in many places making wide avenues thro' the woods; from whence every tree and shrub was torn up, and great branches of trees were driven about in the column as it passed along. It directed its course to Ashley river, down which it came with surprising velocity; in its appearance resembling a column of smoke or vapour, whose motion was very irregular and tumultuous. Its momentum was so great, that Ashley river was ploughed to the bottom, and the channel laid bare. As it came down this river, it made a constant noise like thunder; its diameter being computed about 300 fathoms. It was met at White Point by another of the same kind which came down Cooper's river, but with inferior strength; however, on their meeting together, the agitation of the air was much greater, while the clouds, which were driving in all directions to the place, seemed to be precipitated, and whirled round with incredible velocity. It then fell upon the shipping in the road; entirely destroying some, and damaging others; being scarce three minutes in its passage, though the distance was near two leagues. In that short time it did damage to the amount of L. 20,000; and had not its direction been altered by that gulf which came down Cooper's river, it must have totally destroyed Charlestown, as no obstacle whatever seemed capable of resisting its fury.

WHISKY, a term signifying *water*, and applied in Scotland and in Ireland to a distilled liquor drawn from barley, which is perhaps preferable to any English malt brandy: it is strong, but not pungent, and free from the empyreumatic taste or smell.

WHISPERING-PLACES. See *ACOUSTICS*, n^o 24.

WHIST, a well-known game at cards, which requires great attention and silence; hence the name.

This game is played by four persons, who cut for partners; the two highest and the two lowest are together, and the partners sit opposite to each other: the person who cuts the lowest card is to deal first, giving one at a time to each person, till he comes to the last card, which is turned up for the trump, and remains on the table till each person has played a card. The person on the left hand side of the dealer plays first, and whoever wins the trick is to play again, thus going on till the cards are played out. The ace, king, queen, and knave of trumps, are called *honours*; in case any three of these honours have been played between, or by either of the two partners, they reckon for two points towards the game; and if the four honours have been played between, or by either of the two partners, they reckon for four points towards the game, the game consisting of ten points. The honours are reckoned after the tricks; all above six tricks reckoning also towards the game.

General Rules for playing the Game of Whist.—1. He who is to play first should lead from the strongest suit. If he has a sequence of king, queen, and knave, or queen, knave and ten, he may safely lead the highest of the sequence; but if he has five or six in number, he must begin with the lowest. He must always begin with the highest trump, by which he forces out the superior trumps, and can come in again, to make his strong suit.

2. He should never be afraid to play trumps when he has five in his hand, even of the smallest, although he may not have any good cards of any other suit.

3. With ace and king of any two suits, and only two or three small trumps, the aces and kings should be played out, in order to make as many tricks as possible; and having but two or three small trumps, he should never force his partner to trump, if he finds he cannot follow suit; but endeavour to throw the lead into his partner's hand.

4. He should in general return his partner's lead, unless he has some capital cards of his own.

5. As this game is played with the lurch, that is, to save half the stake, five points must be made before the game is out: he should not venture to play trumps when he is four of the game, unless he is very strong, having at least an honour and three trumps, or ace, king, and two small ones.

6. When the game is scored nine, at which stage the honours reckon for nothing, he should be still more cautious how he plays trumps, even if he is strong in hand, and give his partner an opportunity of trumping the adversaries suits, in case he is deficient in them.

7. If his adversaries are six or seven love of the game, he should play a forward or bold game, that he may have a chance, at the risk of a trick or two, to come up with them. If he has but three trumps and other good cards, he may play trumps, especially if he has a sequence, or queen, knave, and a small one.

8. He should always risk a trick or two when the game is much in his favour; because a new deal is of greater consequence to the adversary than one or two points are to him.

9. When the player finds there is a likelihood of either saving the game or his lurch, he should risk the odd trick; but if the game is five all, and he can make two tricks in his own hand, he should make them, in order to secure the difference of two points, which make the game near two to one in his favour.

10. A good player should begin with a small trump, when he has ace, king, and four small ones; for this reason, if his partner has a better trump than the last player, which is an equal wager but he has, he has a chance of fetching out all the trumps, by having three rounds of them.

11. The odds are always in his favour that his partner holds an honour; consequently if he has king, queen, and four small ones, he should begin with a small one.

12. When queen, knave, and four small trumps are dealt him, he should play a small one first, the odds being in his favour that his partner holds an honour; if he has knave, ten, and four small trumps, he should also begin with a small one, for the same reason.

13. If he has knave, ten, eight, and three small trumps, the knave should be played first, by which means the nine may be prevented from winning a trick, the odds being in his favour that three honours are played in two rounds.

14. If an honour is turned up against him on his left hand, and he has ten, nine, and eight, with two or three small trumps; when he is to play, he should play through the honours with the ten, which will force the dealer to play his honour to a disadvantage, if the dealer does not

choose to leave it to the option of his adversary whether he will pass it or not; but if he has six trumps of a lower denomination, and not ten, nine, and eight, and no honour turned up against him, he should begin with a small one.

15. In general, when he has two capital cards in trumps, and two or three small ones, he should begin with a small one, for the reason assigned in n^o 12.

16. When he has ace, king, knave, and two small trumps, or even one small trump, by first playing the king, and putting the lead into his partner's hand, who will play a trump; judging him to have ace and knave, from his beginning with the king: in this case the knave should be finessed (A), nothing being against him but the queen.

17. If he has knave, ten, eight, and two small trumps, by playing the knave first, it is odds but in two rounds of trumps the nine falls, or he may finesse the eight when his partner returns trumps.

18. With five trumps of a lower denomination, he should begin with the smallest, unless he has a sequence of ten, nine, and eight; then he should begin with the ten.

19. When he has king, queen, ten, and one small trump, he must begin with the king, and wait for his partner's return of the trumps, in order to finesse the ten, by which means he may win the knave.

20. In order to prevent the ten from winning, when he has queen, knave, nine, and one small trump, he must begin with the queen. And in case he has knave, ten, eight, and one small trump, he should begin with the knave, that the nine may not win.

21. If he has ten, nine, eight, and one small trump, he should begin with the ten; thereby he strengthens his partner's hand, leaving it at his option to take it or not.

22. He should begin with a small one, when he has the ten and three small trumps.

23. If he has a good suit, and ace, king, and four small trumps, he must play three rounds of trumps, in order to secure his strong suit from being trumped.

24. When he has king, queen, ten, and three small trumps, he should begin with the king, because he has a chance of the knave's coming down in the second round: and to secure his strong suit, he should not wait to finesse the ten. If he should have queen, knave, and three small trumps, and some good suit to make, he must begin with a small one.

25. If he has knave, ten, eight, and two small trumps, with a strong suit, he should begin with the knave, in order to make the nine fall in the second round; but if he has knave, ten, and three small trumps, with a good suit, he should play a small one first.

26. With ten, nine, eight, and one small trump, provided he has a good suit, he should begin with the ten; by which means he may get the trumps out, and have a chance of making his strong suit.

The following observations will enable a player to know what his partner has no more of a suit which either of them has played. Suppose he leads from queen, ten, nine, and two small cards of any suit, the second hand puts on the knave, his partner plays the eight; in this case, he having queen, ten, and nine, it is a demonstration, if his partner plays well, that he can have no more of that suit. By that discovery, he may play his game accordingly, either by forcing his partner to trump that suit, if he is strong in trumps, or by playing another suit. If he has king, queen, and ten of a suit, and he leads his king, his partner plays the

knave; this also demonstrates he has no more of that suit. If he has king, queen, and many more of a suit, and begins with the king, in some cases it is good play in a partner, when he has the ace and one small card in that suit only, to win the king with the ace; for suppose the partner to be very strong in trumps, by taking the king with the ace, he gets the lead and trumps out, and having cleared the board of trumps, his partner returns his lead; and the ace being out, there is room for him to make that whole suit, which could not have been done if the partner had kept the ace. Suppose he has no other good card in his hand besides that suit, he loses nothing by the ace's taking his king; and if it should so happen that he has a good card to bring in that suit, he gains all the tricks which he makes in that suit by this method of play: as his partner has taken his king with the ace, and trumps out upon it, he has reason to imagine that his partner has one of that suit to return him; for which reason he should not throw away any of that suit, even to keep a king or queen guarded.

Method of playing when an honour is turned up on the right hand.—Suppose the knave is turned up on his right hand, and that he has king, queen, and ten; in order to win the knave, he must begin with the king; by which means, his partner may suppose him to have queen and ten remaining, especially if he has a second lead, and he does not proceed to play the queen.

Suppose the knave turned up as before, and he has ace, queen, and ten, by playing his queen, it answers the purpose of the former rule.

When the queen is turned up on his right hand, and he has ace, king, and knave, by playing his king, it answers the same purpose of the former rule.

In case an honour is turned up on his left hand, supposing he should hold no honour, he should play trumps through the honour as soon as he gets the lead; but if he should hold an honour (except the ace), he must be cautious how he plays trumps, because, in case his partner holds no honour, his adversary will play his own game upon him.

Method of playing the sequences.—The highest in sequences of trumps should be played, unless he has ace, king, and queen; and then he should play the lowest, which informs his partner of the state of his game.

When he has king, queen, and knave, and two small ones, which are not trumps, he should begin with the knave, whether he is strong in trumps or not, as he makes way for the whole suit by getting the ace out.

If he is strong in trumps, and has a sequence of queen, knave, ten, and two small cards of a suit, he should play the highest of his sequence; for if either of the adversaries should trump that suit in the second round, being also strong in trumps, he will make the remainder of that suit, by fetching out their trumps. When he has knave, ten, and nine, and two small cards of a suit, he may play in the like manner.

If king, queen, and knave, and one small card of any suit, is the case, whether strong in trumps or not, he should play the king; and when there are only four in number, the same method of play should be observed by inferior sequences.

When weak in trumps, he should begin by the lowest of the sequence, provided he has five in number, because if his partner has the ace of that suit he will make it. If he has the ace and four small cards of a suit, and weak in trumps, leading from that suit, he should play the ace. When strong in trumps, the game may be played otherwise.

(A) *Finesse*, is to play a small card which may win, keeping the superior card or cards to lay over the right hand adversary.

Whist.

How to make a slam, or win every trick.—Suppose A and B partners against C and D, and C to deal, A to have the king, knave, nine, and seven of hearts, which are trumps, a quart-major in spades, a tierce-major in diamonds, and the ace and king of clubs. Then suppose B to have nine spades, two clubs, and two diamonds. Also suppose D to have ace, queen, ten, and eight of trumps, with nine clubs, and C to have five trumps and eight diamonds. A leads a trump, which D wins, and D is to play a club, which his partner C is to trump; C leads a trump, which his partner D wins; D then will lead a club, which C will trump; and C will play a trump, which D will win; and D having the best trump will play it; after which D having seven clubs in his hand, makes them, so that he slams A and B.

How to play any hand of cards according to the nearest calculations of his partner's holding certain winning cards:

- | | |
|---|------------|
| 1 That he has not one certain winning card, is | 2 to 1 |
| 2 That he has not two certain winning cards, is | 17 to 2 |
| But it is about 5 to 4 that he has one or both, or | 32 to 25 |
| 3 That he has one card out of any three certain winning cards, is about | 5 to 2 |
| 4 That he has not three certain winning cards, is about 31 to 1, or | 631 to 22 |
| 5 That he has not two of them, is about 7 to 2, or | 547 to 156 |
| 6 That he has not one of them, is about 7 to 6, or | 378 to 325 |
| 7 That he holds one or two of them, is in his favour about 13 to 6, or | 481 to 222 |
| 8 And about 5 to 2 that he holds 1, 2, or all three of them. | |

The use of these calculations is for a whist-player to play his cards to the most advantage. For instance,

As the first calculation is two to one that his partner does not hold one certain winning card.—Suppose then a suit is led, of which the second player has the king and a small one only, he should put on the king, because the odds are in his favour that the third player cannot win it. For the same reason, when he is second player, and to lead, he should play a king in preference to a queen, because it is two to one the ace does not take it; but it is five to four the queen will be taken by either ace or king, which may be in the third hand.

According to the second calculation, of its being five to four that his partner holds one certain winning card out of any two: If he has two honours in any suit, he can play to an advantage, knowing it is five to four in favour of his partner's having one of the two honours; and by the same rule, if he is second player, having a queen and one small card, by playing the queen he plays five to four against himself.

It is obvious, from the third calculation, which proves it to be five to two that his partner has one card out of any three certain winning cards, that he who plays the knave second hand, having but the knave and one small card of the same suit, must play five to two against himself, and discovers his game to a great disadvantage; for which reason, he should play the lowest of any sequence which he may hold in his hand, as the knave, if he has king, queen, and knave; the ten, if he has queen, knave, and ten, &c. By so doing, his partner has an opportunity of judging what card to play in that suit, according to the odds for or against him.

From the above calculation, if he has ace, king, and two small trumps, he is entitled to win four tricks out of six,

provided he has four winning cards of any suit; or five tricks out of seven, if he has five winning cards of any suit: by playing two rounds of trumps, and taking out eight of them, it is five to two but his partner has a third trump; and if it should be so, he makes the tricks intended.

WHISTON (William), an English divine of great parts, uncommon learning, and of a singular character, was born at Norton near Twycrosse in the county of Leicester, where his father was rector, in 1667. He was admitted of Clarehall, Cambridge, where he pursued his studies, particularly in the mathematics, and commenced tutor; which his ill health at length forced him to decline. Having entered into orders, he, in 1694, became chaplain to Dr More bishop of Norwich; and in this station he published his first work, intitled, *A New Theory of the Earth, &c.* in which he undertook to prove the Mosaic doctrine of the earth perfectly agreeable to reason and philosophy. This work brought no small reputation to the author. In the beginning of this century he was made Sir Isaac Newton's deputy, and afterwards his successor, in the Lucasian professorship of mathematics; when he resigned a living he had in Suffolk, and went to reside at Cambridge. About this time he published several scientific works, explanatory of the Newtonian philosophy; and he had the honour of being one of the first, if not the very first, who rendered those principles popular and intelligible to the generality of readers. About the year 1710, he was known to have adopted Arian principles, and was forming projects to support and propagate them: among other things, he had translated the Apostolical Constitutions into English, which favoured the Arian doctrine, and which he asserted to be genuine. The consequence was, that he was deprived of his professorship, and banished the university; he nevertheless pursued his scheme, by publishing the next year his *Primitive Christianity Revived*, 4 vols, 8vo. for which the convocation fell upon him very vehemently. On his expulsion from Cambridge, Mr Whiston settled in London; where, without suffering his zeal to be intimidated, he continued to write, and to propagate his *Primitive Christianity*, with as much ardour as if he had been in the most flourishing circumstances. In 1721, a subscription was made for the support of his family, which amounted to 470*l.* For though he drew profits from reading astronomical and philosophical lectures, and also from his publications, which were very numerous, yet these of themselves would have been very insufficient: nor, when joined with the benevolence and charity of those who loved and esteemed him for his learning, integrity, and piety, did they prevent his being frequently in great distress. He continued long a member of the church of England, and regularly frequented its service, though he disapproved of many things in it: but at last he went over to the Baptists, and attended Dr Forster's meeting at Pinner's Hall, Broad-street. Among other performances not specified above, he wrote *Memoirs of his own life and writings*, which contain some curious particulars.

He was remarkable for speaking the plainest truths on every occasion, and to persons of every degree. During the year 1725, that he, with Dr Clarke, Dr Berkeley, and others, had the honour to attend Queen Caroline on a certain day of every week, to talk of the progress of science, her Majesty one evening took occasion to pay him a just compliment on his truth and integrity, requesting that he would, with his usual plainness, point out to her any fault that he might have observed in her conduct. At first he begged to be excused, adding, that few persons could bear to have their faults plainly told to them, and least of all royal personages, who, from their elevation, are necessarily surrounded by flatterers, to whose lips truth is a stranger.

Her Majesty replied, that he was to consider her not as a queen, but as a philosopher; and that philosophy is of very little use, if it cannot enable its professors to bear without offence truths necessary to their own improvement. Upon this he told her, that the greatest fault which he had observed in her conduct, was her indecent behaviour in the house of God, which, he assured her, had made very unfavourable impressions on the minds of many persons, who, coming to town from distant parts of the country, had gone to the chapel to obtain a sight of her majesty, the king, and the royal family. The Queen made no reply; but in about six weeks afterwards renewed her request, that Mr Whitton would point out the most glaring improprieties in her conduct. To this he answered, that he had laid down a maxim from which he could not deviate, never to point out to any person more than one fault at a time, and never to give a second reproof till he had observed some good consequence to have arisen from the first (A). Much to the Queen's honour, she was pleased with this plain-dealing, and continued to think favourably of Mr Whitton. This honest, but whimsical and credulous man, died in 1762, at the advanced age of 95.

WHITBY (Dr Daniel), a very learned English writer, was born in 1633, and bred at Oxford; where, in 1664, he was elected perpetual fellow of his college. He afterward became chaplain to Dr Seth Ward, bishop of Salisbury; who collated him in 1668 to the prebend of Yatebury in that church, and soon after to that of Halborn and Burbach. In 1672 he was admitted chanter of the said church, on the death of Mr John South, and then, or soon after, rector of St Edmund's church in Salisbury. He was made a prebendary of Taunton Regis in 1696, and died in 1726. He was ever strangely ignorant of worldly affairs, even to a degree that is scarcely to be conceived. His writings are numerous, and well known; particularly his Commentary on the New Testament.

WHITBY, a sea-port town in the North Riding of Yorkshire, seated on the river Esk, near the place where it falls into the sea. The houses are neat, strong, and convenient; the number of inhabitants about 9000. Ship-building is their principal manufacture. W. Long. o. 24. N. Lat. 54. 30.

WHITE, one of the colours of natural bodies.

WHITE of the Eye, denotes the first tunic or coat of the eye, called *albuginea*. See **ANATOMY**, n° 142.

WHITE of an Egg. See **ALBUMEN** and **EGG**.

WHITE Friars, a name common to several orders of monks, from being clothed in a white habit.

WHITE Sea, is a bay of the Frozen Ocean, so called in the north part of Muscovy, lying between Russian Lapland and Samoiëda; at the bottom of which stands the city of Archangel. This was the chief port the Russians had before their conquest of Livonia.

WHITE Colour for painting. See **CHEMISTRY**, n° 703.

WHITE Copper. See **CHEMISTRY**, n° 1157.

WHITE Drop, Ward's. See **CHEMISTRY**, n° 746.

WHITE Iron, or *Tin-plate*, iron-plates covered over with tin; for the method of making which, see **LATTEN**.

In 1681 tin plates were manufactured in England by one Andrew Yarranton, who had been sent to Bohemia to learn the method of making them. But the manufacture was soon afterwards discontinued. It was revived again in 1747, and is now arrived at as great, if not greater, perfection in this country than in any other.

WHITE Lead. See **CHEMISTRY**, n° 875.

WHITE Throat, in ornithology. See **MOTACILLA**.

WHITEFIELD (George), the celebrated preacher White-field,
White-
bavea. among the people called *Methodists*, was born in the year 1714, at the Bell in the city of Gloucester, which was then kept by his mother. At about 12 years of age he was put to a grammar-school; but his mother entering into a second marriage, which proved a disadvantageous one, he, when about 15, put on a blue apron, and served her in the capacity of a drawer or waiter. After continuing about a year in this servile employment, she turned over the business to his brother; who marrying, and George not agreeing with his sister-in-law, he left the inn. Some time after, meeting with an old school-fellow, then a servitor in Pembroke college, Oxford, he was induced to attempt getting into the same college in a like capacity, and succeeded. Here Mr Whitefield, who from his own account appears to have always had a strong tincture of enthusiasm in his constitution from his very childhood, distinguished himself by the austere-ities of his devotion, and acquired considerable eminence in some religious assemblies in that city. At the age of 21, the fame of his piety recommended him so effectually to Dr Benson, then bishop of Gloucester, that he made him a voluntary offer of ordination. Immediately after this regular admission into the ministry, Mr Whitefield applied himself to the most extraordinary, the most indefatigable, duties of his character, preaching daily in prisons, fields, and open streets, wherever he thought there would be a likelihood of making profelytes. Having at length made himself universally known in England, he embarked for America, where the tenets of Methodism began to spread very fast under his friends the Wesleys; and first determined upon the institution of the orphan-house at Georgia, which he afterwards effected. After a long course of peregrination, his fortune increased as his fame extended among his followers, and he erected two very extensive buildings for public worship, under the name of *Tabernacles*; one in Tottenham-Court Road, and the other in Moorfields. Here, with the help of some assistants, he continued for several years, attended by very crowded congregations, and quitting the kingdom only occasionally. Besides the two tabernacles already mentioned, Mr Whitefield, by being chaplain to the countess dowager of Huntingdon, was connected with two other religious meetings, one at Bath, and the other at Tunbridge, chiefly erected under that lady's patronage. By a lively, fertile, and penetrating genius, by the most unwearied zeal, and by a forcible and persuasive delivery, he never failed of the desired effect upon his ever crowded and admiring audiences. America, however, which always engaged much of his attention, was destined to close his eyes; and he died at Newberry, about 40 miles from Boston in New England, in 1770.

WHITEHAVEN, a sea-port town of Cumberland, with a market on Thursdays, and one fair on August 1st for merchandise and toys. It is seated on a creek of the sea, on the north end of a great bergh or hill, washed by the tide of flood on the west side, where there is a large rock or quarry of hard white stone, which gives name to the place, and which, with the help of a strong stone-wall, secures the harbour, into which in all barks may enter. It is lately much improved in its buildings, and noted for its trade in pit-coal and salt, there being near it a prodigious coal-mine, which runs a considerable way under the sea. They have a customhouse here; and they carry on a good trade to Ireland, Scotland, Chester, Bristol, and other parts. It is 10 miles south west of Cockermonth, and 289 north-west of London. W. Long. 3. 0. N. Lat. 54. 30.

(A) Bishop Berkeley was present at these conversations, and from his son we received the account which we have given of them. They are likewise mentioned, but not stated so accurately, by Bishop Newton in his own *Life*

Whiteness
||
Whytt.

WHITENESS, the quality which denominates or constitutes a body white.

WHITES, or *FLUOR ALBUS*. See **MEDICINE**, n^o 250.

WHITING, in ichthyology. See **GADUS**.

WHITLOW, or **WHITLOE**. See **SURGERY**.

WHITSUN-FARTINGS, otherwise called *Smoke-fartings* or *Quadrantes Pentecostalis*, a composition for offerings which were anciently made in Whitsun-week by every man in England, who occupied a house with a chimney, to the cathedral church of the diocese in which he lived.

WHITSUNDAY, a solemn festival of the Christian church, observed on the fiftieth day after Easter, in memory of the descent of the Holy Ghost upon the apostles in the visible appearance of fiery cloven tongues, and of those miraculous powers which were then conferred upon them.

It is called *Whitsunday*, or *White-Sunday*; because this being one of the stated times for baptism in the ancient church, those who were baptised put on white garments, as types of that spiritual purity they received in baptism. As the descent of the Holy Ghost upon the apostles happened upon the day which the Jews called *Pentecost*, this festival retained the name of *Pentecost* among the Christians.

Whitsunday Isle, one of the New Hebrides, which lies about four miles to the south, runs in the same direction, and is of the same length, having more sloping exposures than *Aurora*: it appears to be better inhabited, and to contain more plantations.

WHORTLEBERRY. See **VACCINIUM**.

WHYTT (Dr Robert), an eminent physician, born at Edinburgh on the 6th September 1714, was the son of Robert Whytt, Esq; of Bennochy, advocate. This gentleman died six months before the birth of our author, who had also the misfortune to be deprived of his mother before he had attained the seventh year of his age. After receiving the first rudiments of school-education, he was sent to the university of St Andrew's; and after the usual course of instruction there, in classical, philosophical, and mathematical learning, he came to Edinburgh, where he entered upon the study of medicine, under those eminent medical teachers, Monro, Rutherford, Sinclair, Plummer, Alston, and Innes. After learning what was to be acquired at this university, in the prosecution of his studies he visited foreign countries; and after attending the most eminent teachers at London, Paris, and Leyden, he had the degree of Doctor of Physic conferred upon him by the university of Rheims in 1736, being then in the 22d year of his age.

Upon his return to his native country, he had the same honour also conferred upon him by the university of St Andrew's; where he had before obtained, with applause, the degree of Master of Arts.

Not long afterwards, in the year 1737, he was admitted a Licentiate of Medicine by the Royal College of Physicians of Edinburgh; and the year following he was raised to the rank of a Fellow of the College. From the time of his admission as a licentiate, he entered upon the practice of physic at Edinburgh; and the reputation which he acquired for medical learning, pointed him out as a fit successor for the first vacant chair in the university. Accordingly, when Dr Sinclair, whose eminent medical abilities, and persuasive powers of oratory, had contributed not a little to the rapid advancement of the medical school of Edinburgh, found that those conspicuous talents which he possessed could no longer be exerted in the manner which they once had been when he enjoyed bodily vigour unimpaired by age and powers of mind unclouded by disease, he resigned his academical appointments in favour of Dr Whytt.

This admission into the college took place on the 20th of June 1746; and he began his first course of the institutions of medicine at the commencement of the next winter-lesson. The abilities which he displayed from his academical chair, in no particular disappointed the expectations which had been formed of his lectures. The Latin tongue was the language of the university of Edinburgh; and he both spoke and wrote in Latin with singular propriety, elegance, and perspicuity. At that time the system and sentiments of Dr Boerhaave, which, notwithstanding their errors, must challenge the admiration of latest ages, were very generally received by the most intelligent physicians in Britain. Dr Whytt had no such idle ardour for novelties as to throw them entirely aside because he could not follow them in every particular. The institutions of Dr Boerhaave, therefore, furnished him with a text for his lectures; and he was no less successful in explaining, illustrating, and establishing the sentiments of the author, when he could freely adopt them, than in refuting them by clear, connected, and decisive arguments, when he had occasion to differ from him. The opinions which he himself proposed, were delivered and enforced with such acuteness of invention, such display of facts and force of argument, as could rarely fail to gain universal assent from his numerous auditors; but free from that self-sufficiency which is ever the offspring of ignorance and conceit, he delivered his conclusions with becoming modesty and diffidence.

From the time that he first entered upon an academical appointment, till the year 1756, his lectures were confined to the institutions of medicine alone. But at that period his learned colleague Dr Rutherford, who then filled the practical chair, who had already taught medicine at Edinburgh with universal applause for more than thirty years, and who had been the first to begin the institution of clinical lectures at the Royal Infirmary, found it necessary to retire from the fatiguing duties of an office to which the progress of age rendered him unequal. On this crisis Dr Whytt, Dr Monro, sen. and Dr Cullen, each agreed to take a share in an appointment in which their united exertions promised the highest advantages to the university. By this arrangement students, who had an opportunity of daily witnessing the practice of three such teachers, and of hearing the grounds of that practice explained, could not fail to derive the most solid advantages.

In these two departments, the institutions of medicine in the university, and the clinical lectures in the Royal Infirmary, Dr Whytt's academical labours were attended with the most beneficial consequences both to the students and to the university. But not long after the period we have last mentioned, his lectures on the former of these subjects underwent a very considerable change. About this time the illustrious Gaubius, who had succeeded to the chair of Boerhaave, favoured the world with his *Institutiones Pathologicae*. This branch of medicine had indeed a place in the text which Dr Whytt formerly followed; but, without detracting from the character of Dr Boerhaave, it may justly be said, that the attention he had bestowed upon it was not equal to its importance. Dr Whytt was sensible of the improved state in which pathology now appeared in the writings of Boerhaave's successor; and he made no delay in availing himself of the advantages which were then afforded.

In the year 1762, his pathological lectures were entirely new-modelled. Following the publication of Gaubius as a text, he delivered a comment, which was read by every intelligent student with the most unfeigned satisfaction. In these lectures he collected and condensed the fruits of accurate observation and long experience. Enriched by all the

the opportunities of information which he had enjoyed, and by all the discernment which he was capable of exerting, they were justly considered as his most finished production.

For a period of more than twenty years, during which he was justly held in the highest esteem as a lecturer at Edinburgh, it may readily be supposed that the extent of his practice corresponded to his reputation. In fact, he received both the first emoluments, and the highest honours, which could here be obtained. With extensive practice in Edinburgh, he had numerous consultations from other places. His opinion on medical subjects was daily requested by his most eminent contemporaries in every part of Britain. Foreigners of the first distinction, and celebrated physicians in the most remote parts of the British empire, courted an intercourse with him by letter. Besides private testimonies of esteem, many public marks of honour were conferred upon him both at home and abroad. In 1752, he was elected a fellow of the Royal Society of London; in 1761, he was appointed first physician to the king in Scotland; and in 1764, he was chosen president of the Royal College of Physicians at Edinburgh.

But the fame which Dr Whytt acquired as a practitioner and teacher of medicine, were not a little increased by the information which he communicated to the medical world in different publications. His celebrity as an author was still more extensive than his reputation as a professor.

His first publication, An Essay on the Vital and other Involuntary Motions of Animals, although it had been begun soon after he had finished his academical course of medical education, did not come from the press till 1751; a period of fifteen years from the time that he had finished his academical course, and obtained a degree in medicine: but the delay of this publication was fully compensated by the matter which it contained, and the improved form under which it appeared.

The next subject which employed the pen of Dr Whytt was one of a nature more immediately practical. His Essay on the Virtues of Lime-water and Soap in the Cure of the Stone, first made its appearance in a separate volume in 1752. Part of this second work had appeared several years before in the Edinburgh Medical Essays: but it was now presented to the world as a distinct publication with many improvements and additions.

His third work, intitled Physiological Essays, was first published in the year 1755. This treatise consisted of two parts; 1st, An Inquiry into the Causes which promote the Circulation of the Fluids in the very small Vessels of Animals; and 2dly, Observations on the Sensibility and Irritability of the Parts of Men and other Animals, occasioned by Dr Haller's treatise on that subject. The former of these may be considered as an extension and farther illustration of the sentiments which he had already delivered in his Essay on the Vital Motions, while the latter was on a subject of a controversial nature. In both he displayed that acuteness of genius and strength of judgment which appeared in his former writings.

From the time at which his Physiological Essays were published, several years were probably employed by our author in preparing for the press a larger and perhaps a more important work than any yet mentioned, his Observations on the Nature, Causes, and Cure of those Disorders which are commonly called *nervous*, *hypochondriac*, and *hysterical*. This elaborate and useful work was published in the year 1764.

The last of Dr Whytt's writings is intitled, Observations on the Dropsy in the Brain. This treatise did not appear till two years after his death; when all his other works were collected and published in one quarto volume, under

the direction of his son and of his intimate friend the late Sir John Pringle.

Besides these five works, he wrote many other papers, which appeared in different periodical publications; particularly in the Philosophical Transactions, the Medical Essays, the Medical Observations, and the Physical and Literary Essays.

At an early period of life, soon after he had settled as a medical practitioner in Edinburgh, he entered into the married state. His first wife was Miss Robertson, sister to General Robertson governor of New York. By her he had two children; both of whom died in early infancy, and their mother did not long survive them. A few years after the death of his first wife, he married as a second wife Miss Balfour, sister to James Balfour, Esq; of Pilrig. By her he had fourteen children; but in these also he was in some respects unfortunate; for six of them only survived him, three sons and three daughters, and of the former two are since dead. Although the feeling heart of Dr Whytt, amidst the distresses of his family, must have often suffered that uneasiness and anxiety which in such circumstances is the unavoidable consequence of parental affection and conjugal love: yet he enjoyed a large share of matrimonial felicity. But his course of happiness was terminated by the death of his wife, which happened in the year 1764: and it is not improbable that this event had some share in hastening his own death; for in the beginning of the year 1765 his health was so far impaired, that he became incapable of his former exertions. A tedious complication of chronical ailments, which chiefly appeared under the form of diabetes, was not to be resisted by all the medical skill which Edinburgh could afford: and at length terminated in death, on the 15th of April 1766, in the 52d year of his age.

WIEBURGH, a considerable town of Denmark, in North Jutland, with a bishop's see, remarkable for being the seat of the chief court of justice in the province. The hall where the council assemble has the archives of the country, and escaped the terrible fire that happened in the year 1726, and which burned the cathedral-church, that of the Black Friars, the town house, and the bishop's palace: but they have all been rebuilt more magnificent than before. It is seated on the lake Weter, in a peninsula, 25 miles north-west of Sleswick, and 110 north-by-west of Copenhagen. E. Long. 9. 50. N. Lat. 56. 20.

WICKER, signifies made of small twigs.

WICKET, a small door in the gate of a fortified place, &c. or a hole in a door through which to view what passes without.

WICKLIFF (John), the first divine in Europe who had resolution to attempt a reformation of religion, was born about the year 1324, in the parish of Wychiff, near Richmond, in Yorkshire. He was educated at Oxford, first in Queen's, and afterwards in Merton college, of which he was a probationer-fellow. Having acquired the reputation of a man of great learning and abilities, in 1361 he was chosen master of Baliol-hall, and in 1365 constituted warden of Canterbury college, by the founder archbishop Simon de Islip; but was, in 1367, ejected by the regulars, together with three secular fellows. He thought their proceedings arbitrary, and therefore appealed to the pope; but instead of obtaining redress, in 1370 the ejection was confirmed. His disappointment probably contributed somewhat towards his enmity to the see of Rome, or rather to confirm that enmity; for he had long before written against the pope's exactions and corruptions of religion. However, his credit in the university continued; for having taken the degree of doctor in divinity, he read public lectures

Wickliff

Wickliff,
Wicklow.

with great applause; in which he frequently exposed the impositions of the Mendicant friars. About this time he published a defence of his sovereign Edward III. against the pope, who had insisted on the homage to which his predecessor king John had agreed. This defence was the cause of Wickliff's introduction at court, and of his being sent one of the ambassadors in 1374 to Bruges, where they met the pope's nuncios, in order to settle several ecclesiastical matters relative to the pope's authority. In the mean time Wickliff was presented by the king to the rectory of Lutterworth in Leicestershire, and in 1375 he obtained a prebend in the church of Westbury in Gloucestershire. Wickliff continued hitherto, without molestation, to oppose the papal authority; but in 1377 a bull was sent over to the archbishop of Canterbury, and to Courtney bishop of London, ordering them to secure this arch-heretic, and lay him in irons; at the same time the pope wrote to the king, requesting him to favour the bishops in the prosecution: he also sent a bull to Oxford, commanding the university to give him up. Before these bulls reached England Edward III. was dead, and Wickliff, protected by John duke of Lancaster, uncle to Richard II. favoured by the queen-mother, and supported by the citizens of London, eluded the persecution of pope Gregory IX. who died in 1378. In the following year this intrepid reformer presented to parliament a severe paper against the tyranny of Rome, wrote against the papal supremacy and infallibility, and published a book *On the Truth of the Scriptures*, intended to prepare the way for an English translation of them, in which he had made considerable progress. In 1381 he published *Sixteen Conclusions*; in the first of which he ventured to expose the grand article of transubstantiation. These conclusions being condemned by the chancellor of Oxford, Wickliff appealed to the king and parliament; but being deserted by his unsteady patron the duke of Lancaster, he was obliged to make a confession at Oxford; and by an order from the king was expelled the university. He now retired to his living of Lutterworth, where he finished his translation of the bible. This version, of which there are several manuscript copies in the libraries of the universities, British Museum, &c. is a very literal translation from the Latin vulgate. In 1383 he was suddenly struck with the palsy; a repetition of which put an end to his life in December 1384. He was buried in his own church, where his bones were suffered to rest in peace till the year 1423, when, by an order from the pope, they were taken up and burnt. — Besides a number of works that have been printed, he left a prodigious number of manuscripts; an accurate list of which may be seen in bishop Tanner's *Bib. Brit. Hib.* Some of them are in the Bodleian Library, others in the British Museum, &c.

Wickliff was doubtless a very extraordinary man, considering the times in which he lived. His natural sagacity discovered the absurdities and impositions of the church of Rome, and he had the honesty and resolution to promulgate his opinions, which a little more support would probably have enabled him to establish: they were evidently the foundation of the subsequent reformation.

WICKLOW, a county of Ireland, in the province of Leinster; bounded on the north by the county of Dublin; on the east by the Irish Sea; on the south by Wexford; and on the west by Kildare and Catherlough. It is 33 miles in length, 20 in breadth, and indifferently fruitful. It contains 54 parishes, and sends 10 members to parliament.

WICKLOW, the capital of a county of the same name, in Ireland; seated on the sea-side, with a narrow harbour, at the mouth of the river Leitrim, over which stands a rock,

instead of a castle, surrounded by a strong wall, 24 miles wide, south of Dublin. W. Long. 6. 7. N. Lat. 52. 55.

WIDGEON, in ornithology. See ANAS.

WIDOW, a woman who has lost her husband.

WIFE, a married woman, or one joined with, and under the protection of, an husband. See HUSBAND.

ISLE OF WIGHT, an island lying on the south coast of Hampshire, from which it is separated by a narrow channel. It is about 21 miles in length, and 13 in breadth. It is nearly divided into equal parts by the river Mede or Cowes, which rising in the southern angle, enters at the northern, into the channel, opposite the mouth of Southampton Bay. The south coast is edged with very steep cliffs of chalk and freestone, hollowed into caverns in various parts. The west side is fenced with ridges of rocks, of which the most remarkable are those called, from their sharp extremities, the *Needles*. Between the island and the main are various sand-banks, especially off the eastern part, where is the safe road of St Helen's. Across the island, from east to west, runs a ridge of hills, forming a tract of fine downs, with a chalky or marly soil, which feed a great number of fine-sheered sheep. Rabbits are also very plentiful here. To the north of this ridge the land is chiefly pasture: to the south of it is a rich arable country, producing great crops of corn. The variety of prospects which this island affords, its mild air, and the neat manner in which the fields are laid out, render it a very delightful spot. It is devoted almost solely to husbandry, and has no manufactory. It is one of the principal resources of the London market for unmaltd barley. Among its products are to be reckoned a pure white pipe-clay, and a fine white crystalline sand; of the latter of which great quantities are exported for the use of the glass-works in various parts. Its principal town is the borough of Newport: it likewise contains the two small boroughs of Newton and Yarmouth.

WILD-FIRE. See *Wild-FIRE*.

WILDERNESS, in gardening, a kind of grove of large trees, in a spacious garden, in which the walks are commonly made, either to intersect each other in angles, or have the appearance of meanders and labyrinths.

Wildernesses (says Mr Miller) should always be proportioned to the extent of the gardens in which they are made; for it is very ridiculous to see a large wilderness planted with tall trees in a small spot of ground; and, on the other hand, nothing can be more absurd than to see little paltry squares, or quarters of wilderness-work, in a magnificent large garden. As to the situation of wildernesses, they should never be placed too near the habitation, nor so as to obstruct any distant prospect of the country, there being nothing so agreeable as an unconfined prospect: but where, from the situation of the place, the sight is confined within the limits of the garden, nothing can so agreeably terminate the prospect as a beautiful scene of the various kinds of trees judiciously planted; and if it is so contrived that the termination is planted circularly, with the concave towards the sight, it will have a much better effect than if it end in straight lines or angles. The plants should always be adapted to the size of the plantation; for it is very absurd for tall trees to be planted in the small squares of a little garden; and in large designs small shrubs will have a mean appearance. It should also be observed never to plant evergreens amongst deciduous trees; but always to place the evergreens in a wilderness in a separate part by themselves, and that chiefly in sight.

As to the walks, those that have the appearance of meanders, where the eye cannot discover more than twenty or thirty yards in length, are generally preferable to all others,

others, and these should now and then lead into an open circular piece of grass; in the centre of which may be placed either an obelisk, statue, or fountain; and if in the middle of the wilderness there be contrived a large opening, in the centre of which may be erected a dome or banqueting house, surrounded with a green plot of grass, it will be a considerable addition to the beauty of the whole. From the sides of the walks and openings, the trees should rise gradually one above another to the middle of the quarters; where should always be planted the largest growing trees, so that the heads of the trees may appear to view, while their stems will be hid from the sight. Thus, in those parts which are planted with deciduous trees, roses, honeysuckles, spiræa frutex, and other kinds of low-flowering shrubs, may be planted next the walks and openings; and at their feet, near the sides of the walks, may be planted primroses, violets, daffodils, &c. not in a straight line, but so as to appear accidental, as in a natural wood. Behind the first row of shrubs should be planted syringas, alixia frutex, mezerions, and other flowering shrubs of a middle growth; and these may be backed with many other sorts of trees rising gradually to the middle of the quarters.

The part planted with evergreens may be disposed in the following manner, viz. in the first line next the great walks may be placed the laurustinus, boxes, spurce-laurel, juniper, savin, and other dwarf evergreens. Behind these may be placed laurels, hollies, arbutuses, and other evergreens of a larger growth. Next to these may be planted alaternuses, phyllireas, yews, cypresses, Virginian cedars, and other trees of the same growth; behind these may be planted Norway and silver firs, the true pine, and other sorts of the fir growth; and in the middle should be planted Scotch pines, pinaster, and other sorts of the larger growing evergreens; which will afford a most delightful prospect if the different shades of the greens are curiously intermixed.

But beside the grand walks and openings (which should always be laid with turf, and kept well mowed), there should be some smaller serpentine walks through the middle of the quarters, where persons may retire for privacy; and by the sides of these private walks may also be scattered some wood-flowers and plants; which, if artfully planted, will have a very good effect.

In the general design for these wildernesses, there should not be a studied and stiff correspondency between the several parts; for the greater diversity there is in the distribution of these, the more pleasure they will afford.

WILKINS (Dr John), a most ingenious and learned English bishop, was the son of a goldsmith of Oxford, and was born in 1614. He adhered to the parliament during the civil wars, by whom he was made warden of Wadham college in 1648; he married afterwards the sister of Oliver Cromwell, and procured a dispensation to retain his wardenship notwithstanding. Richard Cromwell made him master of Trinity college, Cambridge, from which he was ejected on the Restoration. He then became preacher to Gray's-Inn, rector of St Laurence Jewry, London, dean of Rippon, and in 1668 was promoted to the bishopric of Chester: he died in 1672. Bishop Wilkins thought it prudent to submit to the powers in being; he therefore subscribed to the solemn league and covenant while it was enforced, and was equally ready to swear allegiance to king Charles when he was restored: this, with his moderate spirit toward dissenters, rendered him not very agreeable to churchmen. His mathematical and philosophical works, which contain many ingenious and curious pieces, considering the time when they were written, have been collected in one vol. 8vo. He published also some theological tracts. He was the first president of the Royal Society.

WILL, that faculty of the mind by which it embraces or rejects any thing offered to it. See METAPHYSICS.

WILL, or *last Will*, in law, signifies the declaration of a man's mind and intent relating to the disposition of his lands, goods, or other estate, or of what he would have done after his death. In the common law there is a distinction made between a will and a testament: that is called a *will* where lands or tenements are given; and when the disposition concerns goods and chattels alone, it is termed a *testament*. See TESTAMENT.

Will-with-a-whip, or *Jack-with-a-lantern*, two popular names for the meteor called *ignis fatuus*. See LIGHT, n^o 46.

WILLIAM of MALMSBURY, an historian of considerable merit in the reign of king Stephen; but of whose life few particulars are known. According to Hale and Pitts, he was surnamed *Somerford*, from the county in which he was born. From his own preface to his second book *De Regibus Anglorum*, it appears that he was addicted to learning from his youth; that he applied himself to the study of logic, physic, ethics, and particularly to history. He retired to the Benedictine convent at Malmsbury, became a monk, and was made precentor and librarian; a situation which much favoured his intention of writing the history of this kingdom. In this monastery he spent the remainder of his life, and died in the year 1142. He is one of our most ancient and most faithful historians. His capital work is that intitled *De Regibus Anglorum*, in five books; with an Appendix, which he styles *Historie Novelle*, in two more. It is a judicious collection of whatever he found on record relative to England, from the invasion of the Saxons to his own times.

WILLIAM of Newbury, so called from a monastery in Yorkshire, of which he was a member, wrote a history which begins at the conquest and ends at the year 1197. His Latin style is preferred to that of Matthew Paris; and he is intitled to particular praise, for his honest regard to truth, in treating the fables of Jeffery of Monmouth with the contempt they deserve; as well as for expressing his approbation of Henry II.'s design of reforming the clergy, by bringing them under the regulation of the secular power.

WILLIAM of Wykeham, bishop of Winchester, was born in the village of Wykeham, in the county of Southampton, in 1324. He had his education at Winchester and Oxford. Having continued near six years in the university, his patron Nicholas Wedal, governor of the province of Southampton, took him into his family, and appointed him his counsellor and secretary. He could not have made choice of a fitter person for that employment, no man in that age writing or speaking more politely than Wykeham. For this reason Edington, bishop of Winchester, lord high treasurer of the kingdom, appointed him his secretary three years after, and also recommended him to king Edward III. who took him into his service. Being skilled in geometry and architecture, he was appointed surveyor of the royal buildings, and also chief justice in eyre: he it was who superintended the building of Windsor-castle. He was afterward chief secretary of state, a keeper of the privy-seal; and in 1367 succeeded Edington in the see of Winchester. A little after he was appointed lord high-chancellor and president of the privy-council. That he might well discharge the several functions of his employments, both ecclesiastical and civil, he endeavoured, on one hand, to regulate his own life according to the strictest maxims, and to promote such parish-priests only as were able to give due instructions to their parishioners, and at the same time led exemplary lives: on the other hand, he did all in his power to cause justice to be exactly administered. In 1371 he resigned his chancellorship,

Will,
Wiliant.

William Ioship, and some time after the great seal. Edward being returned to England, after having carried on a very successful war in France, found his exchequer in great disorder. The Duke of Lancaster, one of his sons, at the head of several lords, having brought complaints against the clergy, who then enjoyed most posts in the kingdom, the king removed them from their employments. But the laymen, who were raised to them, behaved so ill, that the king was forced to restore the ecclesiastics. The duke of Lancaster showed strong animosity to the clergy, and set every engine at work to ruin Wykeham. He impeached him of extortion, and of disguising things, and obliged him to appear at the King's-bench. He got such judges appointed as condemned him; and not satisfied with depriving him of all the temporalities of his bishopric, he advised Edward to banish him: but this prince rejected the proposal, and afterward restored to Wykeham all that he had been divested of. Richard II. was but eleven years old when Edward died: whereby the duke of Lancaster had an easy opportunity of reviving the accusations against the bishop of Winchester: nevertheless Wykeham cleared himself. Then he founded two noble colleges, the one in Oxford, the other in Winchester. Whilst he was exerting his utmost endeavours to improve these two fine foundations, he was recalled to court, and in a manner forced to accept of the office of lord high-chancellor in 1389.—Having excellently discharged the duties of that employment for three years, he obtained leave to resign it, foreseeing the disturbances that were going to break out. Being returned to his church, he finished his college, and built there so magnificent a cathedral, that it almost equals that of St Paul's in London. He laid out several sums in things advantageous to the public and to the poor; notwithstanding which, in 1397 he was in great danger; for he and some others were impeached of high-treason in open parliament: however, he was again fully cleared. From that time till his death he kept quiet in his diocese, and there employed himself in all the duties of a good prelate. He died in 1404, in the 81st year of his age.

WILLIAM, the name of several kings of England. See ENGLAND, n° 87—92, and BRITAIN, n° 302.

Fort-WILLIAM, a fortress in the Highlands of Scotland, erected in king William's reign, as was also a small town adjoining, called *Maryburgh*, in honour of his queen. It is situated in Invernessshire, on a narrow arm of the sea called *Loch Eil*, which might easily, by a very short canal, be united to the Western sea. Fort-William is of a triangular form, having two bastions, and is capable of admitting a garrison of 800 men; but could not be defended against an attack, as it is commanded by several hills in the neighbourhood.

WILLIAM'S Fort, is a factory of Asia belonging to the East-India company, seated on one of the branches of the river Ganges, in the kingdom of Bengal. The fort was first built in the shape of an irregular tetragon of brick and mortar; and the town has nothing regular in it, because every one built a house as he liked best, and for his own conveniency. The governor's house is within the fort, and is the best piece of architecture in these parts. Here there are also convenient lodgings for the factors and writers, with store-houses for the company's goods, and magazines for ammunition. About 50 yards from the fort is the church, built by the charity of merchants residing here. The town is called *Calcutta*, and has a pretty good hospital for the sick, though few come out of it alive. It is governed by a mayor and aldermen, as most of the company's factories in the East Indies now are. In 1757 it was sur-

prised by the nabob of Bengal, who took it, and put most of those that had made resistance into a place called the *Black Hole*, where most of them were smothered. This nabob was afterwards killed, and another set up in his room, more friendly to the English; and the factory was re-established. B. Long. 86. o. N. Lat. 22. 27.

Sweet-WILLIAM. See DIANTHUS.

WILLIAMSBURG, a town of North America, in Virginia, and formerly capital of that state. It is situated between two creeks; one falling into James, and the other into York River. The distance of each landing place is about a mile from the town, which, with the disadvantage of not being able to bring up large vessels, and the want of enterprise in the inhabitants, has occasioned its decay. Here is a college, designed for the education of the Indians, but which, on account of their aversion to learning, never answered the purpose. It is 60 miles east of Richmond. W. Long. 76. 30. N. Lat. 37. 10.

WILLIAMSTADT, a sea-port town of Holland. It is a handsome strong place, and the harbour is well frequented. It was built by William prince of Orange in 1585; and in 1732 belonged to the stadtholder of Friesland. The river near which it is built is called *Butterfiet* or *Holland Diep*; and is one of the bulwarks of the Dutch on the side of Brabant, where they always keep a garrison. This place made a gallant defence in 1793 against the French, who were obliged to raise the siege. It is 15 miles north-east of Bergen-op-Zoom, and 12 south-west of Dort. E. Long. 4. 30. N. Lat. 51. 39.

WILLIS (Dr Thomas), a celebrated English physician, was born at Great Bodwin, in Wiltshire, in 1621, and studied at Christ-church college, Oxford. When that city was garrisoned for the king, he, among other scholars, bore arms for his Majesty, and devoted his leisure hours to the study of physic. The garrison of Oxford at length surrendering to the parliament, he applied himself to the practice of his profession; and soon rendered himself famous by his care and skill. He appropriated a room as an oratory for divine service according to the church of England, whither most of the loyalists in Oxford daily resorted. In 1660, he became Sedleian professor of natural philosophy, and the same year took the degree of doctor of physic. In 1664, he discovered the famous medicinal spring at Alstropp, near Brackley. He was one of the first members of the Royal Society, and soon made his name illustrious by his excellent writings. In 1666, after the fire of London, he removed to Westminster; and his practice became greater than that of any of the physicians his contemporaries. Soon after his settlement in London, his only son Thomas falling into a consumption, he sent him to Montpellier in France for the recovery of his health; and it proved successful. His wife also labouring under the same disorder, he offered to leave the town; but she, not suffering him to neglect the means of providing for his family, died in 1670. He died at his house in St Martin's in 1675, and was buried near her in Westminster-abbey. Dr Willis was extremely modest and unambitious, and refused the honour of knighthood. He was remarkably pious: As he rose early in the morning, that he might be present at divine service, which he constantly frequented before he visited his patients, he procured prayers to be read beyond the accustomed times while he lived; and at his death settled a stipend of 20l. *per annum* to continue them. He was a liberal benefactor to the poor wherever he came, having from his early practice allotted part of his profits to charitable uses. He was exact and regular in all his hours: and though his table was the resort of most of the great men of London, yet he was remarkable

able for his plainness, and his being a man of little discourse, complaisance, or society; but he was justly admired for his deep insight into natural and experimental philosophy, anatomy, and chemistry; for his successful practice; and for the elegance and purity of his Latin style. He wrote, 1. A treatise in English, intitled *A plain and easy Method for preserving those that are well from the Infection of the Plague, and for curing such as are infected.* 2. Several Latin works, which were collected and printed at Amsterdam, in 1682, in 2 vols 4to.

WILLUGHBY (Francis), a celebrated natural historian, was the only son of Sir Francis Willughby, knight. He was fond of study from his childhood, and held idleness in abhorrence; he being so great an economist with regard to his time, as not willingly to lose or misapply the least part of it, by which means he attained great skill in all branches of learning, and particularly in the mathematics. But observing that the history of animals was in a great measure neglected by his countrymen, he particularly applied himself to that province; and for this purpose carefully read over what had been written on that subject by others. He then travelled several times over his native country; and afterwards into France, Spain, Italy, Germany, and the Low Countries, attended by his ingenious friend Mr John Ray. It is remarkable, that, notwithstanding the advantages of birth, fortune, and parts, he was as humble as any man of the meanest fortune; was sober, temperate, and chaste; scrupulously just; so true to his word and promise, that a man might venture his estate and life upon it; so faithful and constant to his friend, as never to desert him when fortune frowned upon him; and remarkably pious, patient, and submissive to the divine will. This is the character given of him by Mr Ray, whose veracity none will doubt. This ingenious and learned gentleman died in 1672, at 37 years of age; having impaired his health by his application. He wrote, 1. *Ornithologia libri tres*, folio, which was afterwards translated into English, with an Appendix by Mr Ray, in folio. 2. *Historia Piscium libri quatuor*, folio. 3. Letters of Francis Willughby, Esq; added to Philosophical Letters between the learned Mr Ray and several of his correspondents, published, in 8vo, by William Derham. 4. Several ingenious papers in the Philosophical Transactions.

WILMOT (John), earl of Rochester, a great wit in the reign of Charles II. the son of Henry earl of Rochelle, was born in 1648. He was taught grammar and classical learning at the free-school at Burford; where he obtained a quick relish of the beauties of the Latin tongue, and afterwards became well versed in the authors of the Augustine age. In 1659, he was admitted a nobleman of Wadham college, where he obtained the degree of master of arts. He afterwards travelled through France and Italy; and at his return was made one of the gentlemen of the bed-chamber to the king, and comptroller of Woodstock Park. In 1665, he went to sea, and was in the *Revenge*, commanded by Sir Thomas Tiddiman, when an attack was made on the port of Bergen in Norway; during the whole action he showed the greatest resolution, and gained a high reputation for courage; which he supported in a second expedition, but afterwards lost it in a private adventure with Lord Mulgrave.

Before the earl of Rochester travelled, he had given into the most disorderly and intemperate way of living; at his return, however, he seemed to have got the better of it entirely. But falling into the company of the courtiers, who continually practised these excesses, he became so sunk in debauchery, that he was for five years together so given up to drinking, that during all that time he was never cool enough to be master of himself. His violent love of pleasure, and his disposition to extravagant mirth, carried him to great

excesses. The first involved him in sensuality, and the other led him into many adventures and ridiculous frolics. Once disguising himself so that he could not be known by his nearest friends, he set up in Tower-street for an Italian mountebank, and there dispersed his nostrums for some weeks. He often disguised himself as a porter, or as a beggar, sometimes to follow a mean amour; at other times, he would go about merely for diversion, in odd shapes; and acted his part so naturally, that he could not be known even by his friends. In short, by his constant indulgence in wine, women, and irregular frolics, he entirely wore out an excellent constitution before he was 30 years of age. In October 1679, when recovering from a violent disease, which ended in a consumption, he was visited by Dr Burnet, upon an intimation that such a visit would be agreeable to him. Dr Burnet published an account of his conferences with Lord Rochester; in which it appears, that though he had lived the life of a libertine and atheist, yet he died the death of a penitent Christian. His death happened in 1680; since which time his poems have been various times printed, both separately and together: but when once he obtained the character of a lewd and obscene writer, every thing in that strain was fathered upon him; and thus many pieces not of his writing have crept into the later editions of his works. The author of the Catalogue of Royal and Noble Authors says, he was "a man whom the Muses were fond to inspire, and ashamed to avow, and who practised without the least reserve that secret which can make verses more read for their defects than their merits." Lord Rochester's Poems have much more obscenity than wit, more wit than poetry, and more poetry than politeness." His writings, besides those already mentioned, are, A Satyre against Mankind; Nothing, a poem; Valentinian, a tragedy; Fifty-four Letters to Henry Saville, and others; Seven more to his Wife and Son; a Letter on his deathbed to Dr Burnet. He also left behind him several other papers, and a History of the Intrigues of the Court of Charles II. but his mother, a very devout lady, ordered all his papers to be burned.

WILSON (Florence), known in the republic of letters by the name of *Florentius Volusinus*, was born at Elgin in the shire of Murray in Scotland, and educated in the university of Aberdeen. Travelling to England with an intention to improve his fortune, he had the felicity to be introduced to cardinal Wolfey, who appointed him tutor to one of his nephews. In that capacity he went to Paris, and continued there till the cardinal's death. During his residence in that city he became acquainted with the learned cardinal Bellai, archbishop of Paris, who allowed him a pension, and meant to have appointed him royal professor of the Greek and Latin languages in the university of Paris: but Bellai being disgraced, Wilson's prospects faded with the fortunes of his patron, whom nevertheless he attended on his journey to Rome. Wilson was taken ill at Avignon, and the cardinal proceeded without him. After his recovery, he paid a visit to the celebrated cardinal Sabolet, the Mecænas of his time, who was also bishop of Carpentras, where he then resided. The cardinal was so charmed with his erudition, that he appointed him professor of the learned languages, with a stipend of 100 pistoles per annum.

During his residence at Carpentras, he wrote his celebrated treatise *De Animi Tranquillitate*. Mackenzie says that he afterwards taught philosophy in Italy; and that, being at length desirous of returning to Scotland, he began his journey homeward, was taken ill at Viere in Dauphiny, and died there in the year 1547. He was generally esteemed an accomplished linguist, an admirable philosopher, and an excellent Latin poet. He wrote, beside the above treatise, 1. *Poemata*. Lond. 1619, 4to. 2. *Commentatio quædam*

Wilson,
Wilson.

Wilton.

dam theologica in aphorismos diffusa, per Sebast. Gryph. 3. Philosophiz Aristot. Synopsis, lib. iv.

WILSON (Thomas), lord bishop of Sodor and Man, was born in 1663, at Burton, in the county of Chester. He received the rudiments of his education at the county town, and from thence was removed to the university of Dublin. His allowance at the university was 20 l. a-year; a sum, small as it may now appear, which was in those days sufficient for a sober youth in so cheap a country as Ireland.

His first intention was to have applied to the study of physic; but from this he was diverted by archdeacon Hewetson, by whose advice he dedicated himself to the church. He continued at college till the year 1686, when, on the 29th of June, he was ordained deacon.

The exact time of Mr Wilson's leaving Dublin is not known: but on account of the political and religious disputes of those days, it was sooner than he intended. On the 10th of December, in the same year, he was licensed to the curacy of New Church in Winwick, of which Dr Sherlock, his maternal uncle, was rector. His stipend was no more than 30 l. a-year; but being an excellent economist, and having the advantage of living with his uncle, this small income was not only sufficient to supply his own wants, but it enabled him to supply the wants of others; and for this purpose he set apart one-tenth of his income. In 1692 he was appointed domestic chaplain to William earl of Derby, and tutor to his son James Lord Strange, with a salary of 30 l. a-year. He was soon after elected master of the alms house at Latnam, which brought him in 20 l. a-year more. Having now an income far beyond his expectations, or his wishes, except as it increased his ability to do good, he set apart one fifth of his income for pious uses, and particularly for the poor. In short, as his income increased, he increased the portion of it which was allotted to the purposes of charity. At first he set apart a tenth, then a fifth, afterwards a third, and lastly, when he became a bishop, he dedicated the full half of his revenues to pious and charitable uses.

He had not been long in the service of Lord Derby, before he was offered the valuable living of Buddelworth in Yorkshire; which he refused to accept, as being inconsistent with the resolves of his conscience against non-residence, Lord Derby choosing still to retain him as chaplain and tutor to his son. In 1697 he was promoted, not without some degree of compulsion on the part of his patron, to the bishopric of the Isle of Man; a preferment which he held 58 years. In 1698 he married Mary, daughter of Thomas Patten, Esq; of Warrington. By this lady, who survived her marriage about six years, he had four children; none of whom survived him except the late Dr Wilson, prebendary of Westminster.

"The annual receipts of the bishopric (says the author of his memoirs) did not exceed 300 l. in money. Some necessaries in his house, as spices, sugar, wine, books, &c. must be paid for with money; distressed or shipwrecked mariners, and some other poor objects, required to be relieved with money; but the poor of the island were fed and clothed, and the house in general supplied from his demesnes, by exchange, without money. The poor, who could weave or spin, found the best market at Bishop's-court, where they bartered the produce of their labour for corn. Tailors and shoemakers were kept in the house constantly employed, to make into garments or shoes that cloth or leather which his corn had purchased; and the aged and infirm were supplied according to their several wants. Mr Moore of Douglas informed the editor, that he was once witness to a pleasing and singular instance of the Bishop's attention to some aged poor of the island. As he

was distributing spectacles to some whose eye-sight failed them, Mr Moore expressed his surprize, as he well knew not one of them could read a letter. 'No matter (said the Bishop with a smile), they will find use enough for them; these spectacles will help them to thread a needle, to mend their clothes, or, if need be, to keep themselves free from vermin.'

So great was the bishop's attachment to his flock, that no temptation could seduce him from their service. He more than once refused the offer of an English bishopric. There is an anecdote of his lordship and cardinal Fleury, which does great credit to them both. The cardinal wanted much to see him, and sent over on purpose to inquire after his health, his age, and the date of his consecration, as they were the two oldest bishops, and he believed the poorest, in Europe; at the same time inviting him to France. The bishop sent the cardinal an answer, which gave him so high an opinion of him, that the cardinal obtained an order that no French privateer should ravage the Isle of Man.

This good prelate lived till the year 1755, dying at the advanced age of 93. His works have lately been published in 2 vols 4to.

WILTTON, a market town in Wiltshire, three miles west of Salisbury. It was once so considerable as to give title to the county. It formerly had 12 churches; and Odo, brother-in-law to William I. was bishop of Wilton: only one now remains. It sends members to parliament, and is the place where the knights of the shire are chosen. It has a great manufactory of carpets, which are brought to high perfection. Wilton is famous for lord Pembroke's seat, so well known through Europe for its containing a grand assemblage of the productions of the greatest and most ancient masters in painting and sculpture.—Two fairs are held here annually.

WILTSHIRE, a county of England, bounded on the west by Somersetshire, on the east by Berkshire and Hampshire, on the north by Gloucestershire, and on the south by Dorsetshire and part of Hampshire. The length amounts to 39 miles; its breadth to 30; and its circumference to 140. It contains 29 hundreds, 23 market-towns, 304 parishes, and about 876,000 souls. Besides two members for the shire, and two for the city of Salisbury, each of the following towns sends two members to parliament, viz. Wilton, Downton, Hindon, Heytesbury, Westbury, Calne, Devizes, Chippanham, Malmesbury, Cricklade, Great Bedwin, Ludgershall, Old Sarum, Wootton-Basset, Marlborough.

The air of this county is very healthy, not only in the more low and level parts, but also on the hills. The soil of the vales is very rich, and produces corn and grass in great plenty. The beautiful downs in the south yield the finest pasture for sheep, with which they are overspread. The greatest disadvantage the county labours under is want of fuel, as there are no coal-pits, and but little wood. This county is noted for great quantities of very fine cheese, and for its manufacture of broad cloth, to which it was invited by the great plenty and teneness of its wool. Besides a number of lesser streams, it is watered by the rivers Isis, Kennet, Upper and Lower Avon, Willy, Burne, and Nadder, which are well stored with fish.

WINCHELSEA, a town in Suffex, which has no market, but has one fair on May 14th for cattle and pedlars ware. It was an ancient place, at least the old town, which was swallowed up by the ocean in 1250. It is now dwindled to a mean place, though it retains its privileges, and sends two members to parliament. It is seated on a rocky cliff, on an inlet of the sea; and had a haven, now choked up. It had 18 parish-churches, now reduced to one. The market-house is in the midst of the town, from whence

whence run four paved streets, at the end of which are four ways, which had formerly buildings on each side for a considerable distance. It is 2 miles south-west of Rye, and 7 1/2 south-east of London. It is governed by a mayor and jurats, though it has but about 70 houses. Three of the gates are still standing, but much decayed. E. Long. o. 44. N. Lat. 50. 58.

WINCHELSEA (Anne countess of), a lady of excellent genius, especially in poetry, was maid of honour to the duchess of York, second wife to king James II. and was afterwards married to Heneage, second son of the earl of Winchelsea. One of the most considerable of the countess of Winchelsea's poems was that on the Spleen. A collection of her poems was printed at London in 1713, containing a tragedy never acted, intitled *Aristomenes*. The countess died in 1720 without issue, as her husband did in 1726.

WINCHESTER, the capital of the county of Hampshire in England. It is a very ancient city, supposed to have been built several centuries before Christ. The Romans called it *Fenta Belgarum*, the Britons *Caer Gwent*, and the Saxons *Wintanceaster*; whence came the present name. It stands upon the river Itchin, in a bottom surrounded with chalky hills; and is generally allowed to have been a considerable place in the time of the Romans. Some of the first converts to Christianity are supposed to have lived here. In the castle, near the west-gate, many of the Saxon kings anciently kept their court. The cathedral was founded by Kengulfe, a king of the Mercians; but there were many Christians, and places for their worship here, long before that period. It is a large pile, and has a venerable look, but is not very elegant. Besides the tombs, there are many curious pieces of workmanship in it; the chief of which are, 1. The font, erected in the time of the Saxons. 2. Copper statues of James I. and Charles I. 3. The bishop's throne. 4. The stalls of the dean and prebendaries. 5. The ascent to the choir and altar. 6. The pavement, inlaid with marble of diverse colours, in various figures. 7. The altar-piece, reckoned the noblest in England. 8. The paintings in the windows, especially the great east window. At the hospital of the Holy Cross, every traveller that knocks at the door may claim a manchet of white bread and a cup of beer; of which a great quantity is provided every day for that purpose. This hospital was intended for the maintenance of a master and 30 pensioners, but only 14 are now maintained in it; and the master enjoys a revenue of 800l. a-year. This city is about a mile and a half in compass, and almost surrounded with a wall of flint, has six gates, large suburbs, broad clean streets; but the private houses are in general but ordinary, many of them being very old. The city is interspersed with a great many gardens, which contribute to its beauty and healthiness. The corporation consists of a mayor, high-steward, recorder, aldermen, two coroners, two bailiffs, 24 common-council men, a town-clerk, four constables, and four sergeants at mace; and the city gives title of *marquis* to the duke of Bolton. A Roman highway leads from hence to Alton; and went formerly, as it is thought, from thence to London. The charming downs in the neighbourhood contribute greatly to the health and pleasure of the inhabitants. The river Itchin is navigable for barges from hence to Southampton. W. Long. 1. 21. N. Lat. 51. 5.

WINCKLEMAN (Abbé John), was born at Stendall, in the old Marche of Brandenburg, in 1718. His father was a shoemaker. This wonderful man, to all appearance destined by his birth to superintend a little school in an obscure town of Germany, raised himself to the office of president of antiquities in the Vatican. After having been seven years professor in the college of Seehausen near Salf-

wedel, he went into Saxony, where he resided seven years more, and was librarian to count Bunau at Nothenitz. When he left this place, 1754, he went to Dresden, where he formed an acquaintance with the ablest artists, and particularly with M. Oeser, an excellent painter, and one of the best draughtsmen of the age. In that year he abjured Lutheranism, and embraced the Roman Catholic religion. In September 1755, he set out for Italy, and arrived at Rome in December following. His principal object was to see the Vatican library, and to examine the ruins of Herculaneum.

Mr Winckleman carried with him into Italy a sense of beauty and art, which led him instantly to admire the master-pieces of the Vatican, and with which he began to study them. He soon increased his knowledge; and it was not till after he had thus purified his taste and conceived an idea of ideal beauty, which led him into the greatest secrets of art, that he began to think of the explanation of other monuments, in which his great learning could not fail to distinguish him. His erudition enabled him to fill up his principal plan of writing the "History of Art." In 1756 he planned his "Restoration of Ancient Statues," and a larger work on the "Taste of the Greek Artists;" and designed an account of the galleries of Rome and Italy, beginning with a volume on the Belvedere statues, in the manner of Richardson, who, he says, only ran over Rome. He also intended a history of the corruption of taste in art, the restoration of statues, and an illustration of the obscure points of mythology. All these different essays led him to his "History of Art," and his "Monumenti Inediti." It must, however, be confessed, that the first of these works has not all the clearness and precision that might be expected in its general plan and division of its parts and objects; but it has enlarged and extended the ideas both of antiquaries and collectors. The description of the gems and sulphurs of the Stofch cabinet contributed not a little to extend Mr Winckleman's knowledge. Few persons have opportunities of contemplating such vast collections. The engravings of Lippert and count Caylus are all that many can arrive at. Mr Winckleman's *Monumenti Inediti*, of which he had begun the third vol. 1767, seem to have secured him the esteem of antiquaries. Had he lived, we should have had a work long wished for; a complete collection of the bas-reliefs discovered from the time of Bartoli to the present, the greater part of which are in the possession of cardinal Albani.

When cardinal Albani succeeded to the place of librarian of the Vatican, he endeavoured to get a place for the Hebrew language for Winckleman, who refused a canonry, because he would not take the tonsure. The elector of Saxony gave him, 1761, unsolicited, the place of counsellor Richter, the direction of the royal cabinet of medals and antiquities at Dresden. Upon the death of the Abbé Venuti, 1762, he was appointed president of the antiquities of the apostolic chamber, with power over all discoveries and exportations of antiquities and pictures. This is a post of honour, with an income of 160 scudi *per annum*. He had a prospect of the place of president of antiquities in the Vatican, going to be created at 16 scudi *per month*, and was named corresponding member of the Academy of Inscriptions. The king of Prussia offered him by Col. Quintus Icilius the place of librarian and director of his cabinet of medals and antiquities, void by the death of M. Gautier de la Croze, with a handsome appointment. He made no scruple of accepting the offer; but when it came to the pope's ears, he added an appointment out of his own purse, and kept him at Rome.

In April 1768, he left Rome, to go with M. Cavaceppi over Germany and Switzerland. When he came to Vienna,

Winckle-
man,
Wind. he was so pleased with the reception he met with, that he made a longer stay there than he had intended. But, being suddenly seized with a secret uneasiness and extraordinary desire to return to Rome, he set out for Italy, putting off his visits to his friends in Germany to a future opportunity. As he passed through Trieste, he was assassinated, June 8. 1768, by a wretch named Arcangeli, a native of Campiglio, a town in the territory of Pistoia, with whom he had made an acquaintance on the road. This miscreant had been condemned for a robbery to work in fetters four years, and then to be banished the Austrian territories, on an oath never to return. He had obtained a mitigation of one of his sentences, and retired to Venice; but, changing his quarters backwards and forwards, he was so reduced in circumstances that he at length took up his lodgings at the inn to which the Abbé happened to come. Arcangeli paid such assiduous court to him, that he entirely gained his confidence; and having been favoured with a sight of the valuable presents which he had received at Vienna, formed a design to murder and rob him. He bought a new sharp knife on purpose; and as the Abbé (who had in the most friendly manner invited him to Rome) was sitting down in his chair, early in the morning, he threw a rope over his head, and before he could disengage himself, stabbed him in five different places. The Abbé had still strength to get down to the ground-floor, and call for help; and being laid on a bed in the midst of the most violent pain, he had composure sufficient to receive the last sacraments, and to make his will, in which he appointed cardinal Alexander Albani his residuary legatee, and expired in the afternoon. The murderer was soon after apprehended; and executed on the wheel opposite the inn, June 26.

Abbé Winckleman was a middle-sized man; he had a very low forehead, sharp nose, and little black hollow eyes, which gave him an aspect rather gloomy than otherwise. If he had any thing graceful in his physiognomy, it was his mouth. A fiery and impetuous disposition often threw him into extremes. Naturally enthusiastic, he often indulged an extravagant imagination; but as he possessed a strong and solid judgment, he knew how to give things a just and intrinsic value. In consequence of this turn of mind, as well as a neglected education, a cautious reserve was a quality he little knew. If he was bold in his decisions as an author, he was still more so in his conversation, and has often made his friends tremble for his temerity. If ever man knew what friendship was, that man was Mr Winckleman, who regularly practised all its duties; and for this reason he could boast of having friends among persons of every rank and condition.

WIND is a sensible agitation of the atmosphere, occasioned by a quantity of air flowing from one place to another.

As navigation depends in a great measure upon the direction and force of the winds, as the temperature of climates is greatly influenced by them, and as they are absolutely necessary to preserve the salubrity of the atmosphere, it is not surprising that they have very much engaged the attention of mankind. To be acquainted with the laws by which they are regulated, and to be able to calculate beforehand the consequences of these laws, has been in every age the eager wish of philosophers. But whether it has been owing to an improper method of studying this subject, or to its lying beyond the reach of the human faculties, philosophers have not made that progress in it which the sanguine imaginations of some individuals led them to expect. Many discoveries indeed have been made; and from the numbers and the genius of the philosophers at present engaged in this study, others equally important may be expected.

But, notwithstanding this, many of the phenomena remain unexplained, and a rational and satisfactory theory seems still beyond our reach. It will not be expected, that where philosophers in general have failed, we shall succeed. If we can collect the facts hitherto ascertained, and explain such of them as the late discoveries have enabled us to understand, we trust we shall obtain the indulgence of the Public, though we cannot boast of throwing much new light on this difficult subject.

History of the Winds.

As the winds of the torrid zone differ in several important particulars from those which blow without the tropics, we shall first describe them, and afterwards those of the temperate zones.

I. In those parts of the Atlantic and Pacific oceans which lie nearest the equator, there is a regular wind during the whole year called the *trade-wind*. On the north side of the equator it blows from the north-east, varying frequently a point or two towards the north or east; and on the south side of it, from the south-east; changing sometimes in the same manner towards the south or east. The space included between the second and fifth degree of north latitude is the internal limit of these two winds. There the winds can neither be said to blow from the north nor the south; calms are frequent, and violent storms. This space varies a little in latitude as the sun approaches either of the tropics.—In the Atlantic ocean the trade-winds extend farther north on the American than on the African coast; and as we advance westward, they become gradually more easterly, and decrease in strength*. Their force diminishes likewise as we approach their utmost boundaries. It has been remarked also, that as the sun approaches the tropic of Cancer, the south-east winds become gradually more southerly, and the north-east winds more easterly: exactly the contrary takes place when the sun is approaching the tropic of Capricorn †.

The trade-wind blows constantly in the Indian ocean from the 10th degree of south latitude to near the 30th: But to the northward of this the winds change every six months, and blow directly opposite to their former course. These regular winds are called *monsoons*, from the Malay word *moonssin*, which signifies “a season †.” When they shift their direction, variable winds and violent storms succeed, which last for a month and frequently longer; and during that time it is dangerous for vessels to continue at sea.

The monsoons in the Indian ocean may be reduced to two; one on the north and another on the south side of the equator; which extend from Africa to the longitude of New Holland and the east coast of China, and which suffer partial changes in particular places from the situation and inflection of the neighbouring countries.

1. Between the 3d and 10th degrees of south latitude the south-east trade-wind continues from April to October; but during the rest of the year the wind blows from the north-west †. Between Sumatra and New Holland this monsoon blows from the south during our summer months, approaching gradually to the south-east as we advance towards the coast of New Holland; it changes about the end of September, and continues in the opposite direction till April †. Between Africa and Madagascar its direction is influenced by the coast; for it blows from the north-east from October to April, and during the rest of the year from the south-west †.

2. Over all the Indian ocean, to the northward of the 3d degree of south latitude, the north-east trade-wind blows from October to April, and a south-west wind from April to October †. From Borneo, along the coast of Malacca and

In Ireland the *south-west* and *west* are the grand trade-winds, blowing most in summer, autumn, and winter, and least in spring. The *north-east* blows most in spring, and nearly double to what it does in autumn and winter. The *south-east* and *north-west* are nearly equal, and are most frequent after the south-west and west †.

At Copenhagen the prevailing winds are the *east* and *south-east*; at Stockholm, the *west* and *north* †. In Russia, from an average of a register of 16 years, the winds blow from November to April in the following order :

	West.	N. W.	East.	S. W.	South.	N. E.	N.	S. E.
Days	45	26	23	22	20	19	14	12

And during the other six months,

	West.	N. W.	East.	S. W.	South.	N. E.	N.	S. E.
Days	27	27	19	24	22	15	32	18

The *west* wind blows during the whole year 72 days; the *north-west* 53; the *south-west* and *north* 46 days each. During summer it is calm for 41 days, and during winter for 21*. In Norway the most frequent winds are the *south*, the *south-west*, and *south-east*. The wind at Bergen is seldom directly west, but generally south-west or south-east; a north-west, and especially a north-east wind, are but little known there †.

From the whole of these facts, it appears that the most frequent winds on the south coasts of Europe are the north, the north-east, and north-west; and on the western coast, the south-west: that in the interior parts which lie most contiguous to the Atlantic Ocean, south-west winds are also most frequent; but that easterly winds prevail in Germany. Westerly winds are also most frequent on the north-east coast of Asia.

It is probable that the winds are more constant in the south temperate zone, which is in a great measure covered with water, than in the north temperate zone, where their direction must be frequently interrupted and altered by mountains and other causes.

M. de la Baillie, who was sent thither by the French king to make astronomical observations, informs us, that at the Cape of Good Hope the main winds are the *south-east* and *north-west*; that other winds seldom last longer than a few hours; and that the *east* and *north-east* winds blow very seldom. The *south-east* wind blows in most months of the year, but chiefly from October to April; the *north-west* prevails during the other six months, bringing along with it rain, and tempests, and hurricanes. Between the Cape of Good Hope and New Holland the winds are commonly westerly, and blow in the following order: *north-west*, *south-west*, *west*, *north* †.

In the great South Sea, from latitude 30° to 40° south, the *south-east* trade-wind blows most frequently, especially when the sun approaches the tropic of Capricorn; the wind next to it in frequency is the *north-west*, and next to that is the *south-west*. From south latitude 40° to 50° the prevailing wind is the *north-west*, and next the *south-west*. From 50° to 60° the most frequent wind is also the *north-west*, and next to it is the *west* *.

Thus it appears that the trade-winds sometimes extend farther into the south temperate zone than their usual limits, particularly during summer; that beyond their influence the winds are commonly westerly, and that they blow in the following order: *north-west*, *south-west*, *west*.

Thus have we finished the history of the direction of the winds. In the torrid zone they blow constantly from the north-east on the north side of the equator, and from the south-east on the south side of it. In the north temperate zone they blow most frequently from the south-west; in the

south temperate zone from the north-west, changing, however, frequently to all points of the compass, and in the north temperate zone blowing particularly during spring from the north-east.

As to the velocity of the wind, its variations are almost infinite; from the gentlest breeze to the hurricane, which tears up trees and blows down houses. It has been remarked, that our most violent winds take place when neither the heat nor the cold is greatest; that violent winds generally extend over a great tract of country; and that they are accompanied with sudden and great falls in the mercury of the barometer. The wind is sometimes very violent at a distance from the earth, while it is quite calm at its surface. On one occasion Lunardi went at the rate of 70 miles an hour in his balloon, though it was quite calm at Edinburgh when he ascended, and continued so during his whole voyage. See PNEUMATICS.

For the instruments invented to measure the velocity of the wind, see ANEMOSCOPE and ANEMOMETER.

Theory of the Winds.

THE atmosphere is a fluid surrounding the earth, and extending to an unknown height. Now all fluids tend invariably to a level: if a quantity of water be taken out of any part of a vessel, the surrounding water will immediately flow in to supply its place, and the surface will become level as before; or if an additional quantity of water be poured into any part of the vessel, it will not remain there, but diffuse itself equally over the whole. Such exactly will be the case with the atmosphere. Whatever therefore destroys the equilibrium of this fluid, either by increasing or diminishing its bulk in any particular place, must at the same time occasion a wind.

Air, besides its qualities in common with other fluids, is also capable of being dilated and compressed. Suppose a vessel filled with air: if half the quantity which it contains be drawn out by means of an air-pump, the remainder will still fill the vessel completely; or if twice or three times the original quantity be forced in by a condenser, the vessel will still be capable of holding it.

Rarefied air is lighter, and condensed air heavier, than common air. When fluids of unequal specific gravities are mixed together, the heavier always descend, and the lighter ascend. Were quicksilver, water, and oil, thrown into the same vessel together, the quicksilver would uniformly occupy the bottom, the water the middle, and the oil the top. Were water to be thrown into a vessel of oil, it would immediately descend, because it is heavier than oil. Exactly the same thing takes place in the atmosphere. Were a quantity of air, for instance, to be suddenly condensed at a distance from the surface of the earth, being now heavier than before, it would descend till it came to air of its own density; or, were a portion of the atmosphere at the surface of the earth to be suddenly rarefied, being now lighter than the surrounding air, it would immediately ascend.

If a bladder half filled with air be exposed to the heat of a fire, the air within will soon expand, and distend the bladder; if it be now removed to a cold place, it will soon become flaccid as before. This shows that heat rarefies and that cold condenses air. The surface of the torrid zone is much more heated by the rays of the sun than the frozen or temperate zones, because the rays fall upon it much more perpendicularly. This heat is communicated to the air near the surface of the torrid zone, which being thereby rarefied, ascends; and its place is supplied by colder air, which rushes in from the north and south.

The diurnal motion of the earth is greatest at the equator, and diminishes gradually as we approach the poles, where

it ceases altogether. Every spot of the earth's surface at the equator moves at the rate of 15 geographical miles in a minute; at the 45° of latitude, it moves at about 11½ miles in a minute; and at the 30°, at nearly 13 miles. The atmosphere, by moving continually round along with the earth, has acquired the same degree of motion; so that those parts of it which are above the equator move faster than those which are at a distance. Were a portion of the atmosphere to be transported in an instant from latitude 30° to the equator, it would not immediately acquire the velocity of the equator; the eminences of the earth therefore would strike against it, and it would assume the appearance of an east wind. This is the case in a smaller degree with the air that flows towards the equator, to supply the place of the rarefied air which is continually ascending; and this, when combined with its real motion from the north and south, must cause it to assume the appearance of a north easterly wind on this side the equator, and of a south easterly beyond it.

33
The earth's diurnal motion,

The motion westwards occasioned by this difference in celerity alone would not be great; but it is farther increased by another circumstance. Since the rarefaction of the air in the torrid zone is owing to the heat derived from the contiguous earth, and since this heat is owing to the perpendicular rays of the sun, those parts must be hottest where the sun is actually vertical, and consequently the air over them must be most rarefied; the contiguous parts of the atmosphere will therefore be drawn most forcibly to that particular spot. Now since the diurnal motion of the sun is from east to west, this hottest spot will be continually shifting westwards, and this will occasion a current of the atmosphere in that direction. That this cause really operates, appears from a circumstance already mentioned: when the sun approaches either of the tropics, the trade-wind on the same side of the equator assumes a more easterly direction, evidently from the cause here mentioned; while the opposite trade-wind, being deprived of this additional impulse, blows in a direction more perpendicular to the equator.

34
And the attraction of the moon,

The westerly direction of the trade-winds is still farther increased by another cause. Since the attraction of the sun and moon produces so remarkable an effect upon the ocean, we cannot but suppose that an effect equally great at least is produced upon the atmosphere. Indeed as the atmosphere is nearer the moon than the sea is, the effect produced by attraction upon it ought to be greater. When we add to this the elasticity of the air, or that disposition which it has to dilate itself when freed from any of its pressure, we cannot but conclude that the tides in the atmosphere are considerable. Now since the apparent diurnal motion of the moon is from east to west, the tides must follow it in the same manner, and consequently produce a constant motion in the atmosphere from east to west. This reasoning is confirmed by the observations of several philosophers, particularly of M. Cassin, that in the torrid zone the barometer is always two-thirds of a line higher twice every 24 hours than during the rest of the day; and that the time of this rise always corresponds with the tides of the sea; a proof that it proceeds from the same cause.

§ Journal de Physique, April 1790.

35
Produce the trade-winds.

All these different causes probably combine in the production of the trade-winds; and from their being sometimes united, and sometimes distinct or opposite, arise all those little irregularities which take place in the direction and force of the trade-winds.

Since the great cause of these winds is the rarefaction of the atmosphere by the heat of the sun, its ascension, and the consequent rushing in of colder air from the north and

south, the internal boundary of the trade-winds must be that parallel of the torrid zone which is hottest, because there the ascension of the rarefied air must take place. Now since the sun does not remain stationary, but is constantly shifting from one tropic to the other, we ought naturally to expect that this boundary would vary together with its exciting cause; that therefore when the sun is perpendicular to the tropic of Cancer, the north-east trade-winds would extend no farther south than north latitude 23,5°; that the south-east wind would extend as far north; and that when the sun was in the tropic of Capricorn, the very contrary would take place. We have seen, however, that though this boundary be subject to considerable changes from this very cause, it may in general be considered as fixed between the second and fifth degrees of north latitude.

Though the sun be perpendicular to each of the tropics during part of the year, he is for one half of it at a considerable distance; so that the heat which they acquire while he is present is more than lost during his absence. But the sun is perpendicular to the equator twice in a year, and never farther distant from it than 23½°; being therefore twice every year as much heated, and never so much cooled, as the tropics, its mean heat must be greater, and the atmosphere in consequence generally most rarefied at that place. Why then, it will be asked, is not the equator the boundary of the two trade-winds? To speak more accurately than we have hitherto done, the internal limit of these winds must be that parallel where the mean heat of the earth is greatest. This would be the equator, were it not for a reason which shall now be explained.

It has been shown by astronomers, that the orbit of the earth is an ellipse, and that the sun is placed in one of the foci. Were this orbit to be divided into two parts by a straight line perpendicular to the transverse axis, and passing through the centre of the sun, one of these parts would be less than the other; and the earth, during its passage through this smaller part of its orbit, would constantly be nearer the sun than while it moved through the other portion. The celerity of the earth's motion in any part of its orbit is always proportioned to its distance from the sun; the nearer it is to the sun, it moves the faster; the farther distant, the slower. The earth passes over the smaller portion of its orbit during our winter; which must therefore be shorter than our summer, both on account of this part of the orbit being smaller than the other, and on account of the increased celerity of the earth's motion. The difference, according to Cassini, is 7 days, 23 hours, and 53 minutes. While it is winter in the northern, it is summer in the southern hemisphere; wherefore the summer in the southern hemisphere must be just as much shorter than the winter as our winter is shorter than our summer. The difference therefore between the length of the summer in the two hemispheres is almost 16 days. The summer in the northern hemisphere consists of 190½ days, while in the southern it consists only of 174½. They are to one another nearly in the proportion of 14 to 12,8; and the heat of the two hemispheres may probably have nearly the same proportion to one another. The internal limit of the trade-winds ought to be that parallel where the mean heat of the globe is greatest: this would be the equator, if both hemispheres were equally hot; but since the northern hemisphere is the hottest, that parallel ought to be situated somewhere in it; and since the difference between the heat of two hemispheres is not great, the parallel ought not to be far distant from the equator (A).

The

(A) This parallel could be determined by calculation, provided the mean heat of both the segments into which it divides

The trade-wind would blow regularly round the whole globe if the torrid zone were all covered with water. If the Indian Ocean were not bounded by land on the north, it would blow there in the same manner as it does in the Atlantic and Pacific Oceans. The rays of light pass through a transparent body without communicating any, or at least but a small degree of heat. If a piece of wood be inclosed in a glass vessel, and the focus of a burning glass directed upon it, the wood will be burnt to ashes, while the glass through which all the rays passed is not even heated. When an opaque body is exposed to the sun's rays, it is heated in proportion to its opacity. If the bulb of a thermometer be exposed to the sun, the quicksilver will not rise so high as it would do if this bulb were painted black. Land is much more opaque than water; it becomes therefore much warmer when both are equally exposed to the influence of the sun. For this reason, when the sun approaches the tropic of Cancer, India, China, and the adjacent countries, become much hotter than the ocean which washes their southern coasts. The air over them becomes rarefied, and ascends, while colder air rushes in from the Indian Ocean to supply its place. As this current of air moves from the equator northward, it must, for a reason already explained, assume the appearance of a south-west wind; and this tendency eastward is increased by the situation of the countries to which it flows. This is the cause of the south-west monsoon, which blows during summer in the northern parts of the Indian Ocean. Between Borneo and the coast of China its direction is almost due north, because the country to which the current is directed lies rather to the west of north; a circumstance which counteracts its greater velocity.

In winter, when the sun is on the south side of the equator, these countries become cool, and the north-east trade-wind resumes its course, which, had it not been for the interference of these countries, would have continued the whole year.

As the sun approaches the tropic of Capricorn, it becomes almost perpendicular to New Holland: that continent is heated in its turn, the air over it is rarefied, and colder air rushes in from the north and west to supply its place. This is the cause of the north-west monsoon, which blows from October to April, from the third to the tenth degree of south latitude. Near Sumatra its direction is regulated by the coast: this is the case also between Africa and Madagascar.

The same cause which occasions the monsoons, gives rise to the winds which blow on the west coasts of Africa and America. The air above the land is hotter and rarer, and consequently lighter than the air above the sea; the sea air

therefore flows in, and forces the lighter land atmosphere to ascend. Wind.

The same thing will account for the phenomena of the sea and land breezes. During the day, the cool air of the sea, loaded with vapours, flows in upon the land, and takes the place of the rarefied land air. As the sun declines, the rarefaction of the land air is diminished: thus an equilibrium is restored. As the sea is not so much heated during the day as the land, neither is it so much cooled during the night; because it is constantly exposing a new surface to the atmosphere. As the night approaches, therefore, the cooler and denser air of the hills (for where there are no hills there are no sea and land breezes) falls down upon the plains, and pressing upon the now comparatively lighter air of the sea, causes the land-breeze. And of the sea and land breezes.

The rarefied air which ascends between the second and fifth degrees of north latitude, has been shown to be the principal cause of the trade-winds. As this air ascends, it must become gradually colder, and consequently heavier; it would therefore descend again if it were not buoyed up by the constant ascent of new rarefied air. It must therefore spread itself to the north and south, and gradually mix in its passage with the lower air; and the greater part of it probably does not reach far beyond the 30°, which is the external limit of the trade-wind. Thus there is a constant circulation of the atmosphere in the torrid zone; it ascends near the equator, diffuses itself toward the north and south, descends gradually as it approaches the 30°, and returning again towards the equator, performs the same circuit. It has been the opinion of the greater part of those who have considered this subject, that the whole of the rarefied air which ascends near the equator, advances towards the poles and descends there. But if this were the case, a constant wind would blow from both poles towards the equator, the trade-winds would extend over the whole earth; for otherwise the ascent of air in the torrid zone would very soon cease. A little reflection must convince us that it cannot be true: rarefied air differs nothing from the common air except in containing a greater quantity of heat. As it ascends, it gradually loses this superfluous heat. What then should hinder it from descending, and mixing with the atmosphere below? That there is a constant current of superior air, however, towards the poles, cannot be doubted; but it consists principally of hydrogen gas. We shall immediately attempt to assign the reason why its accumulation at the pole is not always attended with a north wind. Air circulates in the torrid zone.

If the attraction of the moon and the diurnal motion of the sun have any effect upon the atmosphere, and that they have some effect can hardly be disputed, there must be a And moves westward.

vides the globe were known. Let the radius of this globe be = 1, the circumference of a great circle = 6, and consequently the arc of a great circle = 3, and the solid contents of a hemisphere = 2. Since the internal limit of the trade-winds is not far distant from the equator, we may consider that portion of the sphere intercepted between it and the equator as a cylinder, the base of which is the equator, and its height the arc intercepted between the equator and the internal limit of the trade-winds. Let this arc be x , and consequently the cylinder itself = $3x$, equal to the excess of the southern segment into which this internal limit divides the globe above the northern. Let the heat of the northern segment be = n , and that of the southern = s . The southern segment is = $2 + 3x$, the northern = $2 - 3x$. Now let us suppose that the bulk of each segment is reciprocally as its heat, and we shall have this formula, $2 + 3x$:

$$2 - 3x :: n : s. \text{ Wherefore } x = \frac{2n - 2s}{3n + 3s}. \text{ Now if we suppose } n = 14, \text{ and } s = 12.8, \frac{2n - 2s}{3n + 3s} \text{ is } = \frac{2.4}{80.4}.$$

To reduce this value of x to degrees, we must multiply it by 60, since a great circle was made = 6: it gives $1^\circ 48' 17''$ as the internal limit of the trade-wind. This is too small by $2^\circ 11' 33''$. But the value which we have found is only half of the sine of the arc intercepted between the equator and the internal limit; the arc itself would be somewhat greater; besides, the proportion between the heat of the two segments is an assumed quantity, and may probably be greater than their difference in bulk: and one reason for this may be, the great proportion of land in the northern compared with the southern segment. See the *Journal de Physique*, Mai 1791.

Wind. real motion of the air westwards within the limits of the trade-winds. When this body of air reaches America, its further passage westwards is stopp'd by the mountains which extend from one extremity of that continent to the other. From the momentum of this air, when it strikes against the sides of these mountains, and from its elasticity, it must acquire from them a considerable velocity, in a direction contrary to the first, and would therefore return eastwards again if this were not prevented by the trade-winds. It must therefore rush forwards in that direction where it meets with the least resistance; that is, towards the north and south. As air is nearly a perfectly elastic body, when it strikes against the sides of the American mountains its velocity will not be perceptibly diminished, though its direction be changed. Continuing, therefore, to move with the velocity of the equator, when it arrives at the temperate zones it will assume the appearance of a north-east or south-east wind. To this is to be ascribed the frequency of south-west winds over the Atlantic Ocean and western parts of Europe. Whether these winds are equally frequent in the Northern Pacific Ocean, we have not been able to ascertain; but it is probable that the mountains in Asia produce the same effect as those in America.

winds.

It is not impossible that another circumstance may also contribute to the production of these winds. In the article WEATHER, we endeavoured to prove that the annual evaporation exceeds considerably the quantity of rain which falls; and found reason to conclude, therefore, that part of the evaporated water was decomposed in the atmosphere. In that case, the oxygen, which is rather heavier than common air, would mix with the atmosphere; but the hydrogen (a cubic foot of which weighs only 41.41 grains, while a cubic foot of oxygen weighs 593.32 grains) would ascend to the higher regions of the atmosphere.

By what means this decomposition is accomplished (if it takes place at all) we cannot tell. There are probably a thousand causes in nature of which we are entirely ignorant. Whether heat and light, when long applied to vapours, may not be able to decompose them, by uniting with the hydrogen, which seems to have a greater attraction for heat than oxygen has; or whether the electrical fluid may not be capable of producing this effect—are questions which future observations and experiments must determine. Dr Franklin filled a glass tube with water, and passed an electrical shock through it; the tube was broken in pieces, and the whole water disappeared. He repeated the experiment with ink instead of water, and placed the tube upon white paper: the same effects followed; and the ink, though it disappeared completely, left no stain on the paper. Whether the water in these cases was decomposed or not, it is impossible to say; but the supposition that it was, is not improbable. An experiment might easily be contrived to determine the point.

This decomposition would account for the frequency of south-west winds, particularly in summer; for thus new air is furnished to supply the place of that which is forced northwards by the causes already explained. Perhaps it may be a confirmation of this conjecture, that the south-west winds generally extend over a greater tract of country than most other winds which blow in the temperate zones.

What has been said of south-west winds, holds equally with regard to north-west winds in the south temperate zone.

After south-west winds have blown for some time, a great quantity of air will be accumulated at the pole, at least if they extend over all the northern hemisphere: and it appears from comparing the tables kept by some of our late navigators in the Northern Pacific Ocean with similar tables kept in this island, that this is sometimes the case so far as relates to the Atlantic and Pacific Oceans. When this accumulation becomes great, it must, from the nature of fluids, and from the elasticity of air, press with a considerable and increasing force on the advancing air; so that in time it becomes stronger than the south-west wind. This will occasion at first a calm, and afterwards a north wind; which will become gradually easterly as it advances southwards, from its not assuming immediately the velocity of the earth. The mass of the atmosphere will be increased in all those places over which this north-east wind blows: this is confirmed by the almost constant rise of the barometer during a north-east wind.

Whatever tends to increase the bulk of the atmosphere near the pole, must tend also to increase the frequency of north-east winds; and if there be any season when this increase takes place more particularly, that season will be most liable to these winds. During winter the northern parts of Europe are covered with snow, which is melted in the beginning of summer, when the heat of the sun becomes more powerful. Great quantities of vapour are during that time raised, which will augment both the bulk and weight of the atmosphere; especially if the conjecture about the conversion of vapour into air has any foundation. Hence north-east winds are most prevalent during May and June (B).

But it will be said, if this hypothesis were true, the south-west and north-east winds ought to blow alternately, and continue each of them for a stated time; whereas the south-west wind blows sometimes longer and sometimes shorter, neither is it always followed by a north-east wind.

If the conjecture about the decomposition of vapour in the torrid zone be true, the hydrogen which formed a part of it will ascend from its lightness, and form a stratum above the atmospherical air, and gradually extend itself, as additional hydrogen rises, towards the north and south, till at last it reaches the poles. The lightness of hydrogen is owing to the great quantity of heat which it contains: as it approaches the poles it must lose a great part of this heat, and may in consequence become heavy enough to mix with the atmosphere below. Oxygen makes a part of the atmosphere; and its proportion near the poles may sometimes be greater than ordinary, on account of the additional quantity brought thither from the torrid zone. Mr Cavendish mixed oxygen and hydrogen together in a glass jar; and upon making an electrical spark pass through them, they immediately combined, and formed water.

That there is electric matter at the poles, cannot be doubted. The Abbé Chappe informs us, that he saw thunder and lightning much more frequently at Tobolski and other parts of Siberia than in any other part of the world. In the north of Europe the air, during very cold weather, is exceedingly electric: sparks can be drawn from a person's hands and face, by combing his hair, or even powdering

(B) The frequency of north-east winds during these months is the greatest defect in the climate of Scotland, and is felt indeed severely over all Great Britain. In the united states of America, these winds keep pace with the clearing of the land. Some time ago, in Virginia, they did not reach farther than Williamsburgh; now they reach to Richmond, which is situated considerably farther west, and are even beginning to be felt still farther within the country*. Might it not be possible then to prevent the frequency of these winds in this country, by planting trees along the whole east coast? It is a pity that the experiment were not tried; were it to succeed, it would very materially improve the climate.

dering him with a puff. *Æpinus* was an eye-witness to this fact, and to still more astonishing proofs of the electricity of the atmosphere during great colds.

May not the appearance of the aurora borealis be owing to the union of oxygen and hydrogen by the intervention of the electric fluid? That it is an electrical phenomenon at least, can hardly be doubted. Artificial electricity is much strengthened during an aurora, as Mr *Volta* and Mr *Canton* have observed; and the magnetic needle moves with the same irregularity during an aurora that has been observed in other electrical phenomena. This fact we learn from *Bergman* and *De la Lande*. Many philosophers have attempted to demonstrate, that auroræ boreales are beyond the earth's atmosphere; but the very different results of their calculations evidently prove that they were not possessed of sufficient data.

If this conjecture be true, part of the atmosphere near the poles must at times be converted into water. This would account for the long continuance of south-west winds at particular times: when they do so, a decomposition of the atmosphere is going on at the pole. It would render this conjecture more probable, if the barometer fell always when a south-west wind continues long.

If this hypothesis be true, a south-west wind ought always to blow after auroræ boreales; and we are informed by Mr *Winn**, that this is actually the case. This he found never to fail in 23 instances. He observed also, that when the aurora was bright, the gale came on within 24 hours, but did not last long; but if it was faint and dull, the gale was longer in beginning, and less violent, but it continued longer. This looks like a confirmation of our conjecture. Bright auroræ are probably nearer than those which are dull. Now, if the aurora borealis be attended with a decomposition of a quantity of air, that part of the atmosphere which is nearest must first rush in to supply the defect, and the motion will gradually extend itself to more distant parts. Just as if a hole were bored in the end of a long vessel filled with water, the water nearest the hole would flow out immediately, and it would be some time before the water at the other end of the vessel began to move. The nearer we are to the place of precipitation, the sooner will we feel the south-west wind. It ought therefore to begin sooner after a bright aurora, because it is nearer than a dull and faint one. Precipitations of the atmosphere at a distance from the pole cannot be so great as those which take place near it; because the cold will not be sufficient to condense so great a quantity of hydrogen; south-west winds, therefore, ought not to last so long after bright as after dull auroræ. Winds are more violent after bright auroræ, because they are nearer the place of precipitation; just as the water near the hole in the vessel runs swifter than that which is at a considerable distance.

If these conjectures have any foundation in nature, there are two sources of south-west winds; the first has its origin in the trade-winds, the second in precipitations of the atmosphere near the pole (c). When they originate from the first cause, they will blow in countries farther south for some time before they are felt in those which are farther north; but the contrary will take place when they are owing to the second cause. In this last case, too, the barometer will sink considerably; and it actually does so constantly after auroræ, as we are informed by Mr *Madison* †, who paid particular attention to this subject. By keeping accurate meteorological tables in different latitudes, it might easily be discovered whether these consequences be true, and consequently whether the above conjectures be well or ill grounded.

There are also two sources of north-east winds; the first is an accumulation of air at the pole (d), the second a precipitation of the atmosphere in the torrid zone. For the discovery of this last cause we are indebted to Dr *Franklin*. In 1740 he was prevented from observing an eclipse of the moon at Philadelphia by a north-east storm, which came on about seven o'clock in the evening. He was surprised to find afterwards that it had not come on at Boston till near 11 o'clock: and upon comparing all the accounts which he received from the several colonies of the beginning of this and other storms of the same kind, he found it to be always an hour later the farther north-east, for every 100 miles.

"From hence (says he) I formed an idea of the course of the storm, which I will explain by a familiar instance. I suppose a long canal of water stopped at the end by a gate. The water is at rest till the gate is opened; then it begins to move out through the gate, and the water next the gate is first in motion, and moves on towards the gate; and so on successively, till the water at the head of the canal is in motion, which it is last of all. In this case all the water moves indeed towards the gate; but the successive times of beginning the motion are in the contrary way, viz. from the gate back to the head of the canal. Thus, to produce a north-east storm, I suppose some great rarefaction of the air in or near the gulf of Mexico; the air rising thence has its place supplied by the next more northern, cooler, and therefore denser, and heavier air; a successive current is formed, to which our coast and inland mountains give a north-east direction †."

Currents of air from the poles naturally, as has been observed, assume a north-east direction as they advance southwards; because their diurnal motion becomes less than that of the earth. Various circumstances, however, may change this direction, and cause them to become north, or even north-west, winds. The south-west winds themselves may often prove sufficient for this; and violent rains, or great heat,

Cause of
north-west
winds.

(c) We are now rather doubtful whether the first cause here assigned be so general as we at first imagined. The almost constant sinking of the barometer when a south wind blows, seems to indicate, that it is generally occasioned by decompositions of the atmosphere. Nor are we certain that mountains are adequate to produce the effect assigned them.

(d) When the ice, which in Russia accumulates on the insides of the windows of the common people's houses, thaws, it lets loose a quantity of mephitic air, producing all the dangerous effects of charcoal (*Dr Guthrie of the Climate of Russia, Edin. Transf. vol. ii. p. 220.*). May not then a quantity of air be extricated from ice during its thawing? And may not this be another source of north-east winds? We are not ignorant of the experiment which Dr *Garnet* made to discover this (see *Manchester Transactions, vol. iv.*); and that he found that ice in this country sets loose no air in the act of thawing. But Dr *Guthrie* has shown us, in the essay above referred to, that water, by being long exposed to intense cold, changes its nature, and acquires qualities which it had not before. Would it not be worth the while of the philosophers in Russia, and other cold countries, to investigate this a little farther? We would recommend it to the consideration of the ingenious Dr *Guthrie* himself; who, from his situation, has the best opportunities of investigating the matter completely. It is certainly of very great importance, and might lead to discoveries that would remove our present difficulties in meteorology, and enable us to give a satisfactory and useful theory of the weather.

Wind.
54
Why they
are so fre-
quent in
North
America.

heat, by lessening or rarefying the atmosphere in any country, will produce the same effect in countries to the westwards when north winds happen to be blowing.

In North America, the north-west winds become gradually more frequent as we advance northwards. The east coast of this continent, where the observations were made from which this conclusion was drawn, is alone cultivated; the rest of the country is covered with wood. Now cultivated countries are well known to be warmer than those which are uncultivated; the earth in the latter is shaded from the sun, and never heated by his rays. The air, therefore, in the interior parts of America, must be constantly colder than near the east coast. This difference will hardly be perceptible in the southern parts, because there the influence of the sun is very powerful; but it will become gradually greater as we advance northwards, because the influence of the sun diminishes, and the continent becomes broader. Hence north-west winds ought to become more frequent upon the east coast as we advance northwards; and they will probably cease to blow so often as soon as the whole continent of North America becomes cultivated.

55
Causes of
east and
west winds.

Thus have we attempted to explain the causes which produce the more general winds that prevail in the torrid and temperate zones. The east and west winds, when they are not partial and confined to a very small portion of the atmosphere, seem to be nothing else but currents of air brought from the north or south by the causes already mentioned, and prevented from proceeding farther by contrary currents. If these currents have come from the north, they will assume the appearance of east winds; because their diurnal motion will be less than that of the more southern latitudes over which they are forced to remain stationary. The southern currents will become west winds, for a contrary reason. This will furnish us with a reason for the coldness of east winds, compared with west winds. If this account be true, there ought very frequently to be a west wind in a latitude to the south of those places where an east wind blows. This might easily be determined by keeping accurate registers of the winds in different latitudes, and as nearly as possible under the same meridian; and upon the result of these observations the truth or falsehood of the above conjecture must finally rest.

56
Partial
winds.

Besides these more general winds, there are others which extend only over a very small part of the earth. These originate from many different causes. The atmosphere is composed of three different kinds of air, oxygen, azote, and carbonic acid; to which may be added water. Great quantities of each of these ingredients are constantly changing their aerial form, and combining with various substances; or they are separating from other bodies, assuming the form of air, and mixing with the atmosphere. Partial voids, therefore, and partial accumulations, must be continually taking place in different parts of the atmosphere, which will occasion winds varying in direction, violence, and continuance, according to the suddenness and the quantity of air destroyed or produced. Besides these there are many other ingredients constantly mixing with the atmosphere, and many partial causes of condensation and rarefaction in particular places. To these, and other causes probably hitherto unknown, are to be ascribed all those winds which blow in any place besides the general ones already explained; and which, as they depend on causes hitherto at least reckoned contingent, will probably for ever prevent uniformity and regularity in the winds. All these causes, however, may, and probably will, be discovered: the circumstances in which they will take place, and the effects which they will produce, may be known; and whenever

this is the case, the winds of any place may in some measure be reduced to calculation.

It is of importance, in the first place, to know the general winds, and the causes which produce them; they will blow oftenest in every country, continue longest, and in a great measure stamp the nature of the climate. To explain these has been the intention of this essay; and though we have probably failed of success, our attempt, we hope, will not be altogether useless. The facts which are here collected will at least facilitate the labours of the future inquirer. Were accurate observations made over the whole globe of the direction and velocity of the winds, and especially of the time when they begin and cease to blow, so much light would be thrown in a short time upon this important subject, that a theory of the winds might be formed, capable of explaining all the phenomena, and really useful to the human race.

Hot Winds. See SAMUEL.

WIND-Flower. See ANEMONY.

WIND-Mill, a kind of mill, the internal parts of which are much the same with those of a water-mill: from which, however, it differs, in being moved by the impulse of the wind upon its sails or vanes, which are to be considered as a wheel in axis. See MECHANICS, n^o 62.

WIND-Gage. See *Wind-GAGE*.

WIND-Galls, in farriery. See there § xxxiii.

WIND-Gun. See *Air-Gun*.

Instruments for measuring the strength, velocity, &c. of the WIND. See *Wind-GAGE*, *ANEMOMETER*, and *ANEMOSCOPE*.

WIND-Hatch, in mining, a term used to express the place at which the ore is taken out of the mines.

WIND-Shock, a name given by our farmers to a distemper to which fruit-trees, and sometimes timber-trees, are subject. It is a sort of bruise and shiver throughout the whole substance of the tree; but the bark being often not affected by it, it is not seen on the outside, while the inside is twisted round, and greatly injured. It is by some supposed to be occasioned by high winds; but others attribute it to lightning. Those trees are most usually affected by it whose boughs grow more out on one side than on the other. The best way of preventing this in valuable trees, is to take care in the plantation that they are sheltered well, and to cut them frequently in a regular manner while young.

WIND-Taught, in sea-language, denotes the same as stiff in the wind. Too much rigging, high masts, or any thing catching or holding wind aloft, is said to hold a ship wind-taught; by which they mean, that she stoops too much in her sailing in a stiff gale of wind. Again, when a ship rides in a main stress of wind and weather, they strike down her top-masts, and bring her yards down, which else would hold too much wind, or be too much distended and wind-taught.

WIND-Sails, a sort of wide tube or funnel of canvas, employed to convey a stream of fresh air downward into the lower apartments of a ship.

This machine is usually extended by large hoops situated in different parts of its height. It is let down perpendicularly through the hatches, being expanded at the lower end like the base of a cone; and having its upper side open on the side which is placed to windward, so as to receive the full current of wind; which entering the cavity, fills the tube, and rushes downwards into the lower regions of the ship. There are generally three or four of these in our capital ships of war, which, together with the ventilators, contribute greatly to preserve the health of the crew.

WINDAGE of a Gun, is the difference between the diameter of the bore and the diameter of the ball.

WINDLASS, a machine used for raising huge weights, as guns, stones, anchors, &c.

It is very simple, consisting only of an axis or roller, supported horizontally at the two ends by two pieces of wood and a pulley; the two pieces of wood meet at top, being placed diagonally so as to prop each other; the axis or roller goes through the two pieces, and turns in them. The pulley is fattened at top where the pieces join. Lastly, there are two slaves or handspikes which go through the roller, whereby it is turned, and the rope which comes over the pulley is wound off and on the same.

WINDLASS, in a ship, is an instrument in small ships, placed upon the deck, just abaft the fore mast. It is made of a piece of timber six or eight feet square, in form of an axle-tree, whose length is placed horizontally upon two pieces of wood at the ends thereof, and upon which it is turned about by the help of handspikes put into holes made for that purpose. This instrument serves for weighing anchors, or hoisting of any weight in or out of the ship, and will purchase much more than any capstan, and that without any danger to those that heave; for if in heaving the windlass about, any of the handspikes should happen to break, the windlass would fall of itself.

WINDOW, an aperture or open place in the wall of a house to let in the light. See ARCHITECTURE, n^o 78.

The word is Welch, *uynt dor*, signifying the passage for the wind. Window is yet provincially denominated *windor* in Lancashire; i. e. *wind-door*, or the passage for air, as that for people was peculiarly called the *door*.

Before the use of glass became general, which was not till towards the end of the 12th century, the windows in Britain seem generally to have been composed of paper. Properly prepared with oil, this forms no contemptible defence against the intrusions of the weather, and makes no incompetent opening for the admission of the light. It is still used by our architects for the temporary windows of unfinished houses, and not unfrequently for the regular ones of our work-shops. But some of the principal buildings we may reasonably suppose to have been windowed in a superior manner. They could, however, be furnished merely with lattices of wood or sheets of linen, as these two remained the only furniture of our cathedrals nearly to the eighth century; and the lattices continued in some of the meaner towns of Lancashire to the 18th; and in many districts of Wales, and many of the adjoining parts of England, are in use even to the present moment. These seem all to have been fixed in frames that were called *casamenta*, and now therefore *casements* in Wales and Lancashire.

WINDSOR, a borough-town of Berkshire, 22 miles west of London, most remarkable for the magnificent palace or castle situated there on an eminence, which commands the adjacent country for many miles, the river Thames running at the foot of the hill. The knights of the garter are installed in the royal chapel here. It sends two members to parliament. W. Long. o. 36. N. Lat. 51. 30.

WINDWARD, in the sea-language, denotes any thing towards that point from whence the wind blows, in respect of a ship: thus windward-tide, is the tide which runs against the wind.

WINE, an agreeable spirituous liquor, produced by fermentation from those vegetable substances that contain saccharine matter. A very great number of vegetable substances may be made to afford wine, as grapes, currants, mulberries, elder, cherries, apples, pulses, beans, peas, turneps, radishes, and even grass itself. Hence, under the class

of wines or various liquors, come not only wines, absolutely so called, but also ale, cyder, &c.

Wine, however, is in a more particular manner appropriated to the liquor drawn from the fruit of the vine. The process of making wine is as follows: When the grapes are ripe, and the saccharine principle is developed, they are then pressed, and the juice which flows out is received in vessels of a proper capacity, in which the fermentation appears, and proceeds in the following manner: At the end of several days, and frequently after a few hours, according to the heat of the atmosphere, the nature of the grapes, the quantity of the liquid, and the temperature of the place in which the operation is performed, a movement is produced in the liquor, which continually increases; the volume of the fluid increases; it becomes turbid and oily; carbonic acid is disengaged, which fills all the unoccupied part of the vessel, and the temperature rises to the 72,5th degree. At the end of several days these tumultuous motions subside, the mass falls, the liquor becomes clearer, and is found to be less saccharine, more odorant, and of a red colour, from the reaction of the ardent spirit upon the colouring matter of the pellicle of the grape.

The wine is usually taken out of the fermenting vessels at the period when all the phenomena of fermentation have subsided. When the mass is settled, the colour of the liquor is well developed, when it has become clear, and its heat has disappeared; it is put into casks, where, by a second insensible fermentation, the wine is clarified, its principles combine more perfectly together, and its taste and smell become more and more developed. If this fermentation be stopped or suffocated, the gaseous principles are retained, and the wine is brisker, and more of the nature of must.

It appears, from the interesting experiments of the Marquis de Bullion, that the vinous fermentation does not take place unless tartar be present.

The causes of an imperfect fermentation are the following: 1. If the heat be too little, the fermentation languishes, and the saccharine and oily matters are not sufficiently elaborated, and the wine is unctuous and sweet. 2. If the saccharine body be not sufficiently abundant, as happens in rainy seasons, the wine is weak, and the mucilage which predominates causes it to become sour by its decomposition. 3. If the juice be too watery, concentrated and boiling must is added. 4. If the saccharine principle be not sufficiently abundant, the defect may be remedied by the addition of sugar. Macquer has proved that excellent wine may be made of verjuice and sugar; and M. de Bullion has made wine at Bellejames with the verjuice of his vine rows and moist sugar.

There have been many disputes to determine whether grapes should be pressed with the stalks or without. This depends on the nature of the fruit. When they are highly charged with saccharine and mucilaginous matter, the stalk corrects the insipidity of the wine by its bitter principle: but when, on the contrary, the juice is not too sweet, the stalk renders it drier, and very rough.

The colouring principle of wine is of a resinous nature, and is contained in the pellicle of the grape; and the fluid is not coloured until the wine is formed; for until then there is nothing which can dissolve it: and hence it is that white wine may be made of red grapes, when the juice of the grape is expressed, and the husk thrown away. If wine be evaporated, the colouring principle remains in the residue, and may be extracted by spirit of wine. Old wines lose their colour, a pellicle being precipitated, which is either deposited on the sides of the bottles, or falls to the bottom. If

Wine. wine be exposed to the heat of the sun during the summer, the colouring matter is detached in a pellicle, which falls to the bottom: when the vessel is opened, the discolouring is more speedy, and it is effected in two or three days during the summer. The wine thus deprived of its colour is not perceptibly weakened.

4 Vinous fermentation explained. The vinous fermentation has been examined with great accuracy by M. Lavoisier. According to him, the vegetable juice of which wine is to be made consists of oxygen, hydrogen, and carbon, combined with one another in different proportions, so as to form chiefly water and sugar. The fermentation produces a separation of the elements, and a new combination of them; a quantity of the oxygen and carbon combine and fly off in the state of carbonic acid; part of the carbon, oxygen, and hydrogen, combine first with each other, and then all together, to form alcohol; another part forms acetous acid; the water still remains, and a residuum falls to the bottom composed of the three elements combined in other proportions.

5 Ingredients in different wines. The different kinds of wines produced in Europe and other parts of the world are many; the principal of them and their qualities are well known: a catalogue of them would serve no purpose here. We shall, however, subjoin a table of the quantities of the ingredients of the principal kinds from Neumann's Chemistry.

A quart of	Highly rectified Spirit.			Thick, oily unctuous, resinous matter.			Gummy and tartarous matter.			Water.

The colour of wine is frequently artificial; a deep red is almost always the effect of artificial additions, as of the redwoods, elder berries, bilberries, &c. In France no secret is made of these practices, the colouring matters being publicly thrown out after they have been used.

It is well known to be a common practice among wine-

coopers, innkeepers, and other dealers in wine, to adulterate bad wine in order to conceal its defects: if, for instance, the wine be sour, they throw into it a quantity of sugar of lead, which entirely takes away the sour taste. For similar purposes alum is often mixed with wine. Such substances, however, are well known to be extremely pernicious to the human constitution; it becomes of importance therefore to be able to detect them whenever they happen to be contained in wine. Several chemists who have turned their attention to this subject, have furnished us with tests for this purpose.

To discover lead dissolved in wine, boil together in a pint of water an ounce of quicklime and half an ounce of flour of brimstone; and when the liquor, which will be of a yellow colour, is cold, pour it into a bottle, and cork it up for use. A few drops of this liquor being dropt into a glass of wine or cyder containing lead, will change the whole into a colour more or less brown, according to the quantity of lead which it contains. If the wine be wholly free from lead, it will be rendered turbid by the liquor, but the colour will be rather a dirty white than a black brown.

By this test, however, iron is also precipitated when dissolved in wine, and is apt to be taken for lead; a millake which has ruined several honest merchants. The following test is therefore preferable, as not liable to the same inconvenience.

Take equal parts of calcined oyster-shells and crude sulphur in fine powder, and put them in a crucible, which put into a fire, and raise the heat suddenly till it has been exposed to a white heat for 15 minutes. Then take it out, let it cool, beat the ingredients to powder, and put them into a well corked bottle. To prepare the test-liquor, put 20 grains of this powder, together with 120 grains of cream of tartar, and put them into a strong bottle, fill it up with water, boil it for an hour, and let it cool. Cork the bottle immediately, and shake it from time to time. After some hours repose, decant off the clear liquor into an ounce vial, having first put 22 drops of muriatic acid into each vial. Cork these vials accurately with a little wax mixed up with a little turpentine. One part of this liquor, mixed with three parts of suspected wine, will discover the presence of the smallest quantity of lead or copper, by a very sensible black precipitate, and of arsenic by an orange precipitate; but will have no effect on iron, if there be any: the presence of which, however, may be ascertained by adding a little potash, which will turn the liquor black if there be any iron. Pure wine remains limpid after the addition of this liquor.

As this subject is of importance, we shall add M. Fourcroy's observations on the state in which lead exists in wine, and on the methods of discovering its presence: "Of the different principles which compose wine, there was no doubt (says he) but that acids were the only ones which were capable of dissolving oxyd (calx) of lead. But was it the tartarous acid always contained in larger or smaller quantity in wine, or the acetous acid developed in those which have become sharp, and which there is a greater temptation to sweeten? Experience had proved to me that the acidulous tartrate of potash, or the cream of tartar, takes oxyd of lead from the acetous acid, and a precipitate of tartrate of lead is formed; the pure tartarous acid prepared in Scheele's method produces the same effect. In order to understand how the sharp wine which contains these two acids can hold the oxyd of lead in solution, I made the experiments which gave me the following results: 1. The acidulous tartrate (crem. tart.) has no sensible action upon the oxyds of lead; 2. The pure tartarous acid has a slight action upon the oxyds, and forms on their surface a little tartrate of lead (tartarified lead), in

Wine. A solution of wine.

To discover lead dissolved in wine, boil together in a pint of water an ounce of quicklime and half an ounce of flour of brimstone; and when the liquor, which will be of a yellow colour, is cold, pour it into a bottle, and cork it up for use. A few drops of this liquor being dropt into a glass of wine or cyder containing lead, will change the whole into a colour more or less brown, according to the quantity of lead which it contains. If the wine be wholly free from lead, it will be rendered turbid by the liquor, but the colour will be rather a dirty white than a black brown.

Take equal parts of calcined oyster-shells and crude sulphur in fine powder, and put them in a crucible, which put into a fire, and raise the heat suddenly till it has been exposed to a white heat for 15 minutes. Then take it out, let it cool, beat the ingredients to powder, and put them into a well corked bottle.

Fourcroy's observations on the state in which lead exists in wine, and on the methods of discovering its presence: "Of the different principles which compose wine, there was no doubt (says he) but that acids were the only ones which were capable of dissolving oxyd (calx) of lead. But was it the tartarous acid always contained in larger or smaller quantity in wine, or the acetous acid developed in those which have become sharp, and which there is a greater temptation to sweeten? Experience had proved to me that the acidulous tartrate of potash, or the cream of tartar, takes oxyd of lead from the acetous acid, and a precipitate of tartrate of lead is formed; the pure tartarous acid prepared in Scheele's method produces the same effect. In order to understand how the sharp wine which contains these two acids can hold the oxyd of lead in solution, I made the experiments which gave me the following results: 1. The acidulous tartrate (crem. tart.) has no sensible action upon the oxyds of lead; 2. The pure tartarous acid has a slight action upon the oxyds, and forms on their surface a little tartrate of lead (tartarified lead), in

State of lead in wine.

a white powder; 3. Wine which only contains the tartareous acidule, would not have any action upon the semivitrinous oxyd of lead or litharge; 4. Sharp wine which we attempt to sweeten by this oxyd of lead, acts first upon it by the acetous acid it contains; 5. When this acetite of lead is formed, the tartareous acid precipitates it in the form of tartrite of lead: this is proved by the precipitate which the solution of the acetite of lead or sugar of lead forms in the wine; 6. But the acetous acid, if it be in large enough quantity, redissolves the tartrite of lead in the wine just as distilled water would. Bergman has pointed out this solution of tartrite of lead in acetous acid for distinguishing the tartareous salt from the sulfat of lead (*vitriol of lead*); 7. As this solution of tartrite of lead in the acetous acid is much quicker, and more easy in sharp wines than in distilled water and vinegar, it is probable, that the cause of this difference depends upon the citric and malic acids which I have found in wine, and which I shall take notice of again on another occasion; 8. Litharged wine then, or wine sweetened with lead, contains tartrite dissolved in the acetous acid, and perhaps at the same time in the malic and citric acids.

"It was necessary afterwards to know the properties of this combination. What experience has taught me is as follows: I particularly examined the tartrite of lead and its solution in acetous acid. The tartrite of lead is scarcely at all soluble in water; it is in the form of powder, or of small white grains which have no sensible taste; when it is dissolved in vinegar, the vinegar is softened, its sharpness is diminished remarkably, and the solution takes a slight sweetish taste, much less strong than that of the pure acetite of lead. This taste proves that the union of the tartrite of lead with vinegar is not only a solution like that of salt in water, by which the properties of the salt are not changed, but a combination which gives occasion to new properties. It is a kind of a triple salt, different from those we have hitherto known, formed of two acids and of one base; whereas the other triple salts described hitherto are composed of one acid and two bases. I name this new triple salt *aceto-tartrite of lead*. The acetous acid adheres to it more than water in a common solution: what is remarkable in this combination is, that the two acids appear to adhere to the base with an equal force, although they have a different attraction for it: nothing is necessary to produce this equilibrium, but to unite first the oxyd of lead with the acid to which it adheres the most strongly, and afterwards to put this first compound in contact with the weaker acid.

"It was necessary, in order to discover easy and certain methods of ascertaining the presence of lead in wine, to examine with care the properties and phenomena of the decompositions of the aceto-tartrite of lead. Fixed alkalis and ammoniac (*volatile alkali*) precipitate from this salt an oxyd of lead, which is of a greyish white colour; but as they occasion a precipitate in pure wine, they cannot be of any use. The sulphuric (*viurlic*) acid decomposes the aceto-tartrite of lead, and forms with it instantly sulfat of lead; which being very little soluble, and very heavy, is precipitated. The oxalic, or pure saccharine acid, and the acedulous oxalat, or the salt of sorrel of the shops, likewise decompose this salt, and take from it the lead. The oxalat of lead is precipitated in great abundance: these two acids, the sulphuric and oxalic acids, not producing any precipitate in pure wine, are very proper to show the presence of lead in wine. The sulfat and oxalat of lead, when they are precipitated from wine, are coloured, whereas they are very white when they are formed in distilled water; but their red or brown colour does not prevent us from discovering them by a very simple method. If the precipitates be collected

with care, and are cautiously heated upon a coal with a blow-pipe, they smoke, become white, exhale vapours, pass successively thro' the states of the red and yellow oxyds of lead, and at length are reduced into metallic globules at the instant they are perceived to be agitated by a very evident effervescence: if we cease to blow at this instant, we obtain globules upon the charcoal. In order to this, it is necessary, however, that the charcoal be solid, and be not cracked, and that we should not have blowed too strongly; otherwise the globules would be absorbed, and would disappear. The sulfat of lead requires a longer time to be reduced than the oxalat of the same metal, and there is a greater hazard of losing the metallic particles, which, beside, are in small quantity.

"To these two first processes, already sufficiently certain of themselves, I wished to be able to add one which might be capable of pointing out instantly the presence of lead, by an appearance belonging exclusively to this metal, and which might unite to this advantage that of manifesting very small quantities of it. Distilled water impregnated with sulphurated hydrogenous gas, or hepatic gas, extricated from solid alkaline sulphurets (*livers of sulphur*) by acids, presented me with these properties. This solution blackens very deeply that of the aceto-tartrite of lead, and renders $\frac{1}{1000}$ th of this salt in water or in wine very sensible. The sensibility of this reactive is such, that we may dilute litharged wine with a sufficient quantity of water to take away almost entirely the colour of the wine, and this reactive will still produce a very manifest alteration. The sulphurated water has, besides, the advantage not to occasion any change in the wines which do not contain a metallic substance, and it is not precipitated by the acids of wine, like the solutions of alkaline sulphurets. In order to procure this reactive pure, it is necessary to prepare it at the instant of the experiment, by receiving in a vial full of distilled water, and inverted upon a shelf of a small hydro-pneumatic apparatus, filled with distilled water, the sulphurated hydrogenous gas, separated from the solid sulphuret of potash by the sulphuric or muriatic acid, and first filtered through water in another vial; when the second vial contains the third of its volume of the sulphurated hydrogenous gas, the gas is shaken strongly with the water, which fills the two-thirds of the vial; and when the absorption is over, the test liquor is prepared. This reactive changes very quickly in the air: it is necessary to make it the moment it is to be employed, and to keep it in a vessel quite full and well corked. If there were any fear that the black colour and the precipitation by the gaseous sulphurated water should not be sufficient to prove the presence of lead in spirituous liquors, I would observe, that this fear would be diminished by employing the three reactives mentioned in this memoir, and by depending only on the correspondent effects of these three reactives: but all suspicion would be removed, by reducing the three precipitates by the blow-pipe, and obtaining globules of lead from each of them."

Some years ago, the Academy of Lyons proposed the following prize-question, What is the best method of ascertaining the presence and the quantity of *alum* dissolved in wine, especially in very deep coloured red wine? The prize was gained by M. J. S. Berand. From his experiments, it appears that a mixture of lime-water and wine in any proportion whatever, will at the end of 12 or 15 hours furnish a quantity of crystals, which may be separated by filtration, and that these crystals will be easiest discovered when the quantities of wine and lime-water are equal; but that wine containing alum dissolved in it, will not form crystals when mixed with lime-water, but merely deposits a muddy sediment. To know therefore whether any wine contains alum

Wine. or not, we have only to mix a small quantity of it with lime-water: if crystals are formed, it contains no alum; if not, it does. Again, if wine contains alum, the residuum that remains after filtration will, as it dries, split into quadrilateral ferments, which will detach themselves from the paper which contains them; but if the wine contains no alum, the residuum, after it is dry, will remain united and attached to the paper. If one measure of wine and two thirds of a measure of lime-water deposit crystals, we are certain that if the wine contains alum, the proportion of that alum to the wine will be less than 1 to 1152; if, when equal parts of wine and lime-water are mixed, no crystals be deposited, we may be sure that more than $\frac{1}{256}$ th part of the mass of wine consists of alum.

A great proportion of the wine consumed in this country is brought from Spain and Portugal; government has always discouraged the importation of French wines by heavy taxes. We are not sure how far such conduct is founded on good policy, as the French wines are confessedly the best, and might be the cheapest; but such is the jealousy and enmity that has always subsisted between Britain and France, that both nations have been contented to injure themselves provided they could do a greater injury to their neighbours. Besides, the advantages which Britain derives from the Portugal trade are very great, and it would not be easy perhaps to secure them on any other terms.

53
Directions
for the
treatment
of import-
ed wines.

It may be worth while to insert here a few directions about the treatment of wines after they have been imported into this country.—On landing, the less they are exposed the better; for they are affected by the seasons, and more or less by climate. March and April are the proper times for shipping wines from France, and they will be landed in England and Ireland in the same degree of temperature. The great art in keeping wines is to prevent their fretting, which is done by keeping them in the same degree of heat. In spring and fall, the wines in Bourdeaux are subject to changes that may be dangerous, if not prevented by necessary rackings: these changes are solely the effect of the seasons. If wines are chilled, and of course turn sour, from being shipped and landed in cold weather, they will soon recover by putting them in a warm vault, well covered with saw-dust. As soon as they are in the vault, they ought to be covered up. But if shipped and landed in summer, if the smallest degree of fermentation be found on them, it will be requisite to dip the bung clothes in brandy, and leave the bungs loose for some days, to give it time to cool; and if in a fortnight or three weeks the fermentation do not cease, and the wine become bright, it will be proper to rack it (matching the hogheads well with brimstone), and force it with the whites of eight eggs. If it then becomes fine, bung it tight, and let it remain so until it is bottled. If wines new landed are wanted soon for the bottle, it will be necessary to force them immediately, and let them remain bunged close for at least a month, to recover from the forcing, or if two months the better; for wines bottled in high order come much sooner into drinking than if bottled when flat, which all wines are after forcing. Wine must never be bottled the least sour, which produces a tendency to fret; and if bottled in this state, will never come in order, but may possibly be lost: for this there is no remedy but repeated rackings; and care must be taken (after rinsing the hogheads well and drawing them) to burn a good piece of match in them. This cools the wine, and there is no danger of hurting the colour, for it recovers it in a little time: but if it did, it is absolutely necessary; for if wine is suffered to continue on the fret, it will wear itself to nothing. Wines bottled in good order may be fit to drink in six months; but they are not in perfection before twelve: from that to two years they may continue so; but

it would be improper to keep them longer, for wines in general have not the body they had formerly, from the vines being too much forced.

It sometimes happens that wines scuddy and stubborn will not fall with one or even two forcings. It will then be proper to give them five or six gallons of good strong wine, and force them with the whites of a dozen eggs, with a tea-spoonful of sand produced from sawing marble, or a small spoonful of fine salt. Bottled wine in winter should be well covered with saw-dust, and if the vaults are cold and damp, strew it deep on the floor; if saw-dust is thrown upon the hogheads, and their sides are bedded some inches thick, it will keep them from the fret.

The same treatment is to be regarded with white wines, except that they require to be higher matched, particularly Muscat wines; such as Frontignac, Beziers, &c. which being often sweetened with honey, are very subject to fret; and these only frequent rackings, with a great deal of brimstone, can cool. Hermitage, from not being sufficiently dried, and possessing more richness than claret, is also very liable to come on the fret, and will require much the same treatment as the Muscat wines. Attention should be had to bottle in fine weather, when the wind is north; but to avoid cold or frosty weather. The months of April and October are favourable. The best time to bottle port wine is four years after the vintage, and to keep them two years in bottle before you begin to use them. When wines are racked, and the lees immediately passed thro' flannel bags into close-necked jars, and directly bottled, there will be very little lost by rackings, as the wine when fine may serve for filling up.

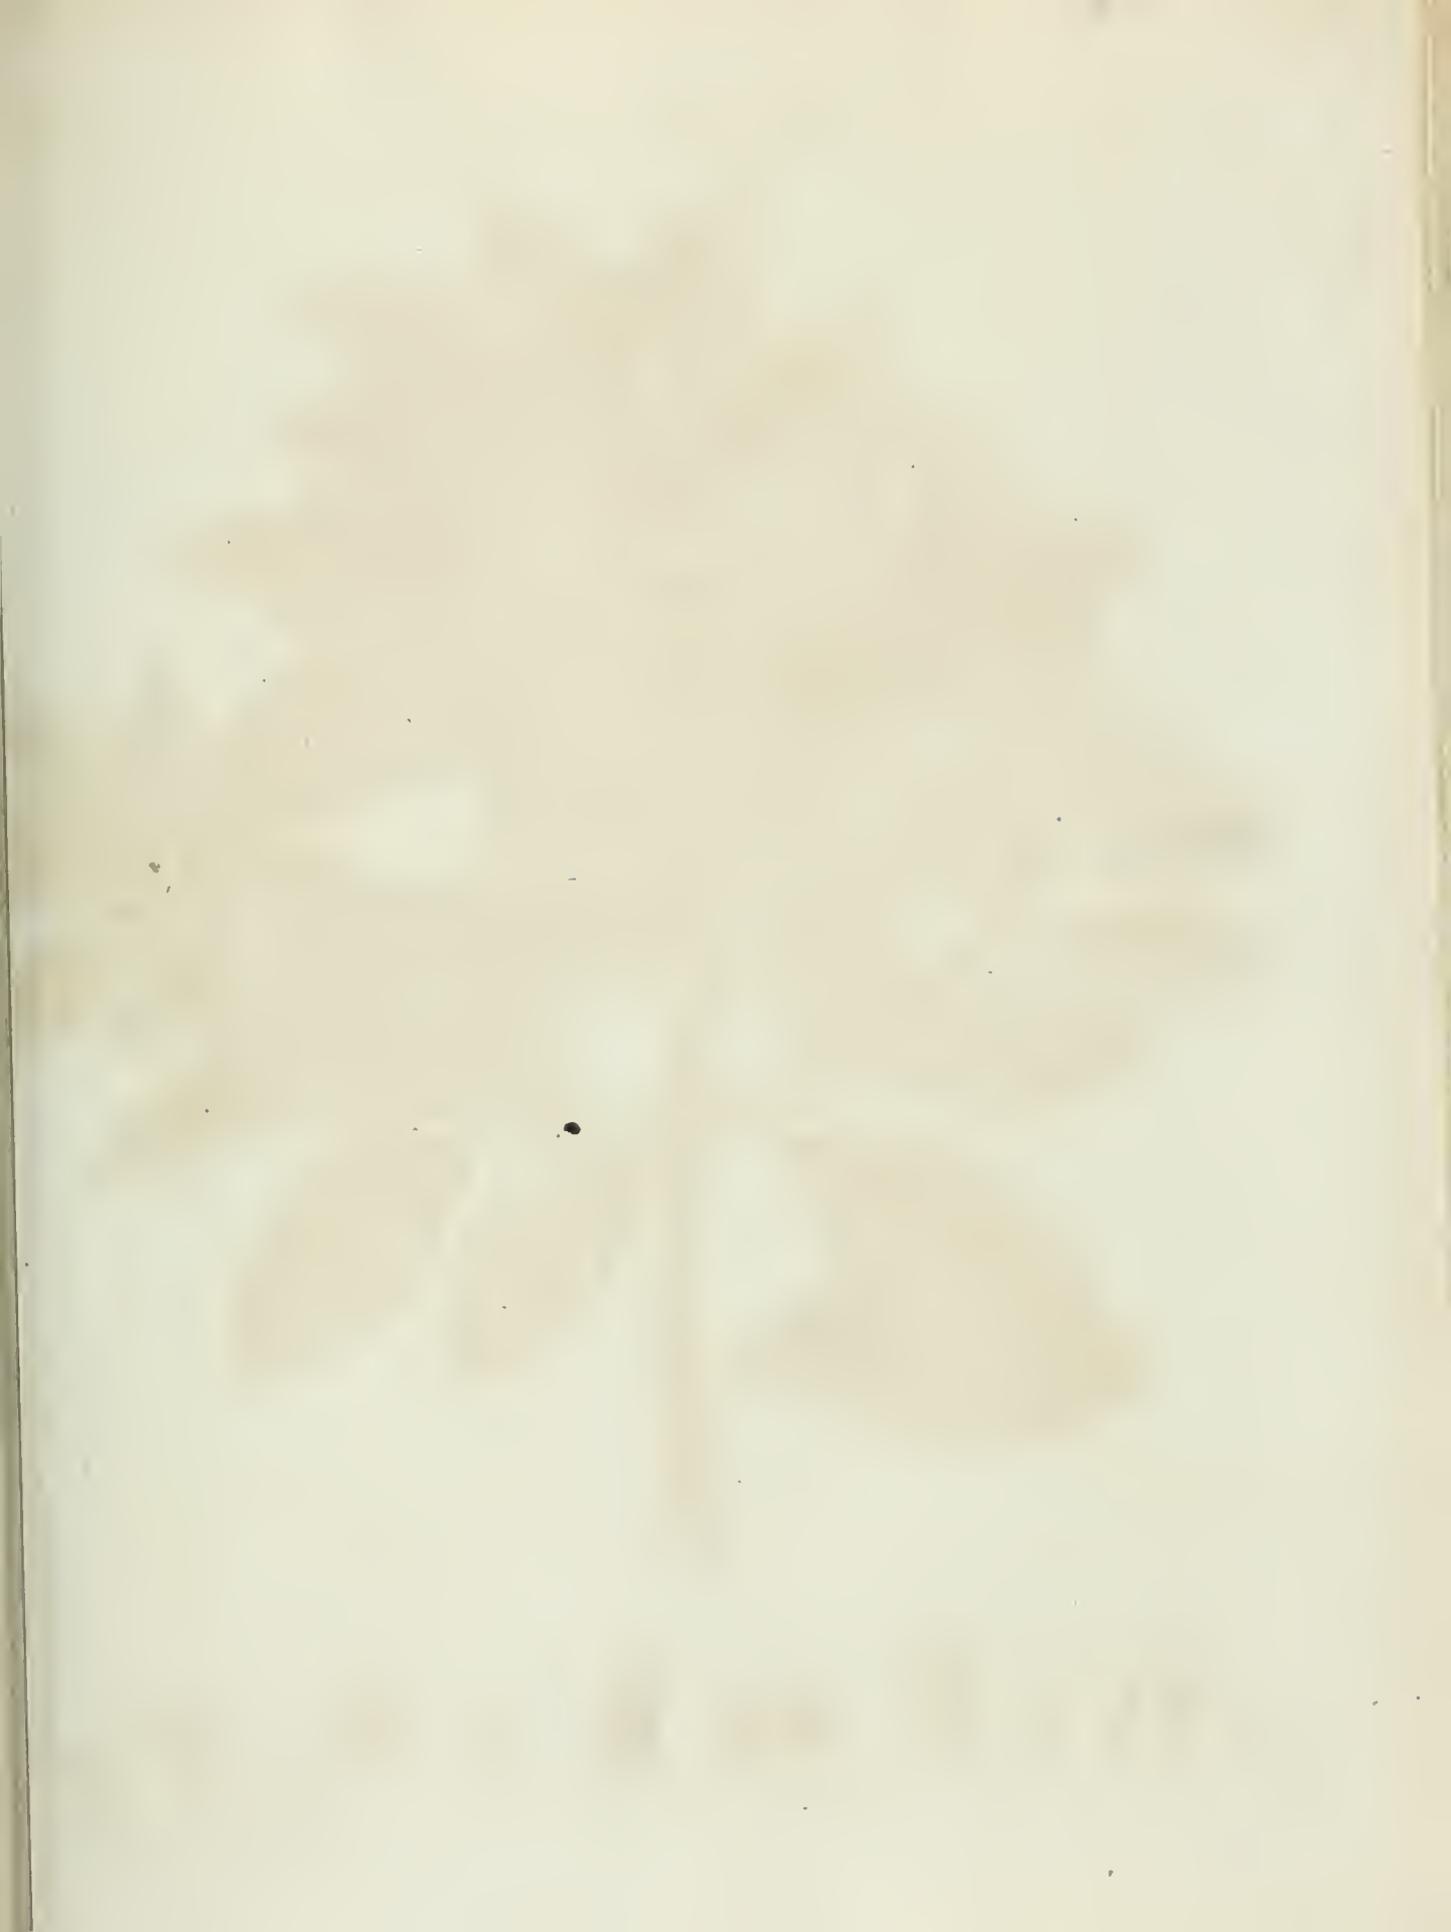

When wines are destined for warm climates, it may be proper to rinse the hogheads with brandy; and in bottling many rinse the bottles and corks with it. Wines that have remained a certain time (three or four months) in a vault, and made less or more lee, ought never to be sent into the country without first racking them, otherwise they may be liable to fret; and if bottled in that state, may risk being lost.

Wines which may be ordered for immediate drinking will be forced on the shipping, and in a few weeks after they are landed will be fit for the bottle. The forcings proper for claret are the whites of a dozen eggs, beat up with a tea-spoonful of fine salt, and well worked with a forcing rod. Take care to use no bad egg. This is for one hog-head.

The forcing for white wine is isinglas dissolved in wine. One ounce is sufficient for two hogheads. No salt is to be used in forcing the white wines. See *Craft on Wines*, 8vo, 1788.

We shall insert here the following receipt for making ¹⁴ Raisin-wine.—To a 20 gallon vessel take 100 pounds of raisins; pick off the stalks, chop them grossly, and put them into an open tub more wide than deep. Add two parts in three of the water to them, and let them stand 15 days, stirring them well every day. Then strain and press them, putting aside the liquor that runs from them. Add the remainder of the water to the raisins that have thus been pressed, and let it stand upon them one week, frequently stirring them as before. Then press off the liquor, and add it to what you first collected; putting both runnings together into your vessel, together with one quart of brandy. To colour it, burn three-fourths of a pound of sugar into a small quantity of the liquor, and add this to the wine. When the liquor in the barrel has done singing, stop the vessel close, and let it stand till fit to be bottled. The greater the quantity which the vessel holds, and the longer it is kept in the wood, the better will it be.

WINE-Press, a machine contrived to squeeze the juice out of

A. Bell. Pin. Nat. Sculptor. fecit.

of grapes, and consisting of several pieces of timber, variously disposed, which compose three bodies of timber-work, closely united to the axis, which serves as a swing whereby it may be moved by the vice. Of these there are different sizes as well as different constructions; for an account of which, illustrated by figures, see Miller's Gardener's Dictionary, article *WINE-Press*.

Spirit of WINE, or *alcohol*, a name given by chemists to every ardent spirit produced by distillation. See *CHEMISTRY-Index*.

WING, that part of a bird, insect, &c. whereby it is enabled to fly. See *BIRD* and *ORNITHOLOGY*.

WINGS, in military affairs, are the two flanks or extremes of an army, ranged in form of a battle; being the right and left sides thereof.

WINTER, one of the four seasons or quarters of the year. See *SEASON*, &c.

Winter commences on the day when the sun's distance from the zenith of the place is greatest, and ends on the day when its distance is at a mean between the greatest and least.

Under the equator, the winter as well as other seasons return twice every year; but all other places have only one winter in the year: which in the northern hemisphere begins when the sun is in the tropic of Capricorn, and in the southern hemisphere when in the tropic of Cancer; so that all places in the same hemisphere have their winter at the same time.

WINTER-Berry. See *PHYSALIS*.

WINTERA, in botany: A genus of plants of the class of *polyandria*, and order of *pentagonia*; and in the natural system arranged under the 12th order, *Holoraceæ*. The calyx is three-lobed; there are six or twelve petals; there is no style; the fruit is a berry, which is club-shaped as well as the germen. There are two species; the *aromatica* and *granadensis*.

Wintera aromatica, is one of the largest forest-trees upon Terra del Fuego; it often rises to the height of 50 feet. Its outward bark is on the trunk grey and very little wrinkled, on the branches quite smooth and green. The branches do not spread horizontally, but are bent upwards, and form an elegant head of an oval shape. The leaves come out, without order, of an oval elliptical shape, quite entire, obtuse, flat, smooth, shining, of a thick leathery substance, evergreen, on the upper side of a lively deep green colour, and of a pale bluish colour underneath, without any nerves, and their veins scarcely visible; they are somewhat narrower near the footstalks, and there their margins are bent downwards. In general, the leaves are from three to four inches long, and between one and two broad; they have very short footstalks, seldom half an inch long, which are smooth, concave on the upper side, and convex underneath. From the scars of the old footstalks the branches are often tuberculated.

The peduncles, or footstalks for the flowers, come out of the *axille foliorum*, near the extremity of the branches; they are flat, of a pale colour, twice or three times shorter than the leaves; now and then they support only one flower, but are oftener near the top divided into three short branches, each with one flower. The bractæe are oblong, pointed, concave, entire, thick, whitish, and situated one at the basis of each peduncle.

There is no calyx; but in its place the flower is surrounded with a spathaceous gem, of a thick leathery substance, green, but reddish on the side which has faced the sun: before this gem bursts, it is of a round form, and its size is that of a small pea. It bursts commonly so, that one side is higher than the other, and the segments are pointed. The corolla

consists always of seven petals, which are oval, obtuse, concave, erect, white, have small veins, and are of an unequal size, the largest scarcely four lines long; they very soon fade, and drop off almost as soon as the gem bursts. The filaments are from 15 to 30, and are placed on the flat end side of the receptacle; they are much shorter than the petals, and gradually decrease in length towards the sides. The antheræ are large, oval, longitudinally divided into two, or as if each was made up of two oblong antheræ. The germina are from three to six, placed above the receptacle, turbinate, or of the shape of an inverted fig; flat on the inside, and somewhat higher than the stamina; they have no styles, but terminate in a stigma, which is divided into two or three small lobes.

Dr Solander, to whom the world is indebted for the description, never saw the fruit in its perfectly ripe state; but could conclude from the unripe fruit which he saw in abundance, that each germen becomes a separate seed-vessel, of a thick fleshy substance, and unilocular; and in each the rudiments of three, four, or five seeds were plainly discernible. See Plate DXL. where n^o 1. represents the spathaceous gem, after it is burst open. 2. The same. 3. The same (*a*) with the corolla (*b*) remaining within it. 4. One of the petals spread out. 5. The stamina (*a*) and the pistilla (*b*) after the gem and the corolla are taken away. 6. The outside of an anthera (*a*) with its filament (*b*). 7. The inside of the same. 8. The germina (*a*) situated on the centre of the receptacle, after the stamina have been removed; the lobated stigma (*b*). 9. The convex or outermost side of a germen (*a*) with its stigma (*b*). 10. The inside of the same. 11. A germen cut open longitudinally, so as to show the rudiments of the seeds. 12. A germen cut through transversely.

The weather is much more severe in the climate where these trees are natives than in Britain; here, therefore, it is thought they would thrive very well.

The bark of the wintera, or winter's cinnamon, brought over by the Dolphin, in respect to figure, exactly resembles that which was delineated by Clusius. The pieces are about three or four inches square, of different degrees of thickness, from a quarter to three quarters of an inch. It is of a dark brown cinnamon colour; an aromatic smell, if rubbed; and of a pungent hot spicy taste, which is lasting on the palate, though imparted slowly. It has the name of *winter's cinnamon*, from a faint resemblance in colour and flavour to that grateful aromatic, though differing from it greatly in every other respect. This bark is only brought to us from the Straits of Magellan, and is the produce of the tree above described; much celebrated as an antiscorbutic by the first discoverers, but unknown in the practice of physic, no quantity, except as a curiosity, having been brought to Europe till the return of the ships sent out on the expeditions to the South Seas. The bark which was substituted in the room of this is the *canella alba* of the shops. See *CANELLA*.

From several experiments made by Dr Morris, the cortex magellanicus appears to be an atringent of a particular kind, and therefore likely to be of use in several manufactures. Water is the proper solvent of this bark; though the saline, gummy, and resinous parts are so blended in it, as in saffron and some other vegetables, that it parts with them readily in proof and rectified spirits of wine, though not in so great a quantity.

The infusion and decoction of this bark were of so grateful an aromatic bitter taste, that it seems likely to be a pleasant vehicle for some of the nauseous drugs. With this view, on substituting the powder of this bark for the cardamom seeds in making the infusion of senna, as directed in the London Dispensatory, the nauseous smell and taste of

Wire that excellent purgative was so effectually covered, as to be scarcely distinguished by the nicest palate. Tincture of rhubarb also prepared with this bark instead of cardamoms seemed far less disagreeable.

WIRE, a piece of metal drawn through the hole of an iron into a thread of a fineness answerable to the hole it passed through.

Wires are frequently drawn so fine as to be wrought along with other threads of silk, wool, flax, &c.

The metals most commonly drawn into wire are gold, silver, copper, and iron. Gold-wire is made of cylindrical ingots of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller, till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes one of the distinguishing characters of gold, is nowhere more conspicuous than in this gilt wire. A cylinder of 48 ounces of silver, covered with a coat of gold, only weighing one ounce, as Dr Halley informs us, is usually drawn into a wire, two yards of which weigh no more than one grain; whence 98 yards of the wire weigh no more than 49 grains, and one single grain of gold covers the 98 yards; so that the ten thousandth part of a grain is above one-eighth of an inch long.

WIRE of Lapland. The inhabitants of Lapland have a sort of shining slender substance in use among them on several occasions, which is much of the thickness and appearance of our silver-wire, and is therefore called, by those who do not examine its structure or substance, *Lapland wire*. It is made of the sinews of the rein deer, which being carefully separated in the eating, are, by the women, after soaking in water and beating, spun into a sort of thread, of admirable fineness and strength, when wrought to the smallest filaments; but when larger, is very strong, and fit for the purposes of strength and force. Their wire, as it is called, is made of the finest of these threads covered with tin. The women do this business; and the way they take is to melt a piece of tin, and placing at the edge of it a horn, with a hole through it, they draw these sinewy threads, covered with the tin, through the hole, which prevents their coming out too thick covered. This drawing is performed with their teeth; and there is a small piece of bone placed at the top of the hole, where the wire is made flat; so that we always find it rounded on all sides but one, where it is flat.

This wire they use in embroidering their clothes as we do gold and silver; they often sell it to strangers, under the notion of its having certain magical virtues.

WISDOM, usually denotes a higher and more refined notion of things immediately presented to the mind, as it were, by intuition, without the assistance of ratiocination.

Sometimes the word is more immediately used, in a moral sense, for what we call *prudence*, or *discretion*, which consists in the soundness of the judgment, and a conduct answerable thereto.

WISDOM of Solomon, one of the books of the Apocrypha. It abounds with Platonic language, and was probably written after the Chaballistic philosophy was introduced among the Jews.

WIT, is a quality of certain thoughts and expressions, much easier perceived than defined. According to Mr Locke, wit lies in the assemblage of ideas, and putting those together with quickness and variety, wherein can be found any resemblance or congruity, thereby to make up pleasant pictures and agreeable visions to the fancy. Mr Addison limited this definition considerably, by observing, that every resemblance of ideas does not constitute wit, but those only which produce delight and surprise. Mr Pope defined wit to be a quick conception and an easy delivery: while, ac-

ording to a late writer, it consists in an assimilation of distant ideas.

The word *wit* originally signified *wisdom*. A *witte* was anciently a *wise man*: the *wittenagemot*, or Saxon parliament, an assemblage of wise men. So late as the reign of Elizabeth, a man of pregnant *wit*, of great *wit*, was a man of vast judgment. We still say, *in his wits*, *out of his wits*, for in or out of sound mind. The word, however, is now applied in a more limited sense.

Without attempting to expose the inaccuracy of the definitions above mentioned, or hazarding a definition of our own where so many eminent men have failed, we shall endeavour to show in what true wit consists.

It is evident that wit excites in the mind an agreeable surprise, and that this is owing entirely to the strange assemblage of related ideas presented to the mind. This end is effected, 1. By debasing things pompous or *seemingly* grave; 2. By aggrandising things little or trifling; 3. By setting ordinary objects in a particular and uncommon point of view, by means not only remote but apparently contrary. Of so much consequence are surprise and novelty, that nothing is more tasteless, and sometimes disgusting, than a joke that has become stale by frequent repetition. For the same reason, even a pun or happy allusion will appear excellent when thrown out extempore in conversation, which would be deemed execrable in print. In like manner, a witty repartee is infinitely more pleasing than a witty attack: for though, in both cases, the thing may be equally new to the reader or hearer, the effect on him is greatly injured, when there is access to suppose that it may be the slow production of study and premeditation. This, however, holds most with regard to the inferior tribes of witticisms, of which their readiness is the best recommendation.

We shall illustrate these observations by subjoining a specimen or two of each of these sorts of wit:

Of the first sort, which consists in the debasement of things great and eminent, Butler, amongst a thousand other instances, hath given us those which follow:

And now had Phœbus in the lap
Of Thetis taken out his nap:
And, like a lobster boil'd, the morn
From black to red began to turn.

Hudibras, part ii. canto 2.

Here the low allegorical style of the first couplet, and the simile used in the second, afford us a just notion of this lowest species, which is distinguished by the name of the *ludicrous*. Another specimen from the same author you have in these lines:

Great on the bench, great in the saddle,
That could as well bind o'er as swaddle,
Mighty he was at both of these,
And styl'd of *war*, as well as *peace*:
So some rats of amphibious nature,
Are either for the *land* or *water*.

Ibid. part i. canto 1.

In this coarse kind of drollery, those laughable translations or paraphrases of heroic and other serious poems, wherein the authors are said to be travestied, chiefly abound.

The second kind, consisting in the aggrandisement of little things, which is by far the most splendid, and displays a soaring imagination, these lines of Pope will serve to illustrate:

As Berecynthia, while her offspring vie
In homage to the mother of the sky,
Surveys around her in the blest abode,
An hundred sons, and every son a god:
Not with less glory mighty dulness crown'd,
Shall take thro' Grubstreet her triumphant round;

And

And her Parnassus glancing o'er at once,
Behold a hundred sons, and each a dunce.

This whole similitude is spirited. The parent of the celestials is contraited by the daughter of night and chaos; heaven by Grubstreet; gods by dunces. Besides, the parody it contains on a beautiful passage in Virgil adds a particular lustre to it. This species we may term the *thrausical*, or the *mock-majestic*. It affects the most pompous language, and sonorous phraseology, as much as the other affects the reverse, the vilest and most grovelling dialect.

To this class also we must refer the application of grave reflections to mere trifles. For that *great* and *serious* are naturally associated by the mind, and likewise little and trifling, is sufficiently evinced by the common modes of expression on these subjects used in every tongue. An apposite instance of such an application we have from Philips:

My galligaskins, that have long withstood
The winter's fury and encroaching frosts,
By time subdued, (*What will not time subdue!*)
An horrid chasm disclose. *Splendid Shilling.*

Of the third species of wit, which is by far the most multifarious, and which results from what may be called the queerness or singularity of the imagery, we shall give a few specimens that will serve to mark some of its principal varieties. To illustrate all would be impossible. The first shall be where there is an apparent contrariety in the things she exhibits as connected. This kind of contrast we have in these lines of Garth:

Then Hydrops next appears amongst the throng;
Bloated and big she slowly sails along:
But like a miser in excess she's poor,
And pines for thirst amidst her watery store.
Dispensary.

A second sort is, where the things compared are what with dialecticians would come under the denomination of *disparates*, being such as can be ranked under no common genus. Of this we shall subjoin an example from Young:

Health chiefly keeps an Atheist in the dark;
A fever argues better than a *Clarke*:
Let but the logic in his pulse decay,
The Grecian he'll renounce, and learn to pray.
Universal Passion.

A third variety in this species springs from confounding artfully the proper and the metaphorical sense of an expression. In this way, one will assign as a motive what is discovered to be perfectly absurd, when but ever so little attended to; and yet, from the ordinary meaning of the words, hath a specious appearance on a single glance. Of this kind we have an instance in the subsequent lines:

While thus the lady talk'd, the knight
Turn'd th' outside of his eyes to white,
As men of inward light are wont
To turn their optics in upon't.

Hudibras, part iii. canto 1.

For whither can they turn their eyes more properly than to the light?

A fourth variety, much resembling the former, is when the argument or comparison (for all argument is a kind of comparison) is founded on the supposal of corporeal or personal attributes in what is strictly not susceptible of them; as in this,

But Hudibras gave him a twitch
As quick as lightning in the breech,
Just in the place where honour's lodg'd,
As wise philosophers have judg'd:

Because a kick in that place more
Hurts honour than deep wounds before.

Ibid. part ii. canto 3.

The fifth, and only other variety which we shall mention, is that which arises from a relation, not in the things signified, but in the signs of all relations, no doubt the slightest. Identity here gives rise to puns and clinches; resemblance to quibbles, cranks, and rhimes: Of these it is quite unnecessary to exhibit specimens.

WIT (John de), a celebrated pensioner of Holland, and one of the greatest politicians of his time, was the son of Jacob de Wit, burgomaster of Dort, and was born in 1625. He became well skilled in civil law, politics, mathematics, and other sciences; and wrote a treatise on the Elements of Curved Lines, published by Francis Schooten. Having taken his degree of doctor of law, he travelled into foreign courts, where he became esteemed for his genius and prudence. At his return to his native country in 1650, he became pensionary of Dort, then counsellor-pensionary of Holland and West Friesland, intendant and register of the fleets, and keeper of the great seal. He was thus at the head of affairs in Holland; but his opposition to the establishment of the office of stadtholder, which he thought a violation of the freedom and independence of the republic, cost him his life, when the prince of Orange's party prevailed. He and his brother Cornelius were assassinated by the populace at the Hague in 1674, aged 47.

WITCH, a person guilty of witchcraft.

WITCHCRAFT, a supernatural power which persons were formerly supposed to obtain the possession of by entering into a compact with the devil. They gave themselves up to him body and soul; and he engaged, that they should want for nothing, and that he would avenge them upon all their enemies. As soon as the bargain was concluded, the devil delivered to the witch an imp, or familiar spirit, to be ready at a call, and do whatever it was directed. By the assistance of this imp and the devil together, the witch, who was almost always an old woman, was enabled to transport herself in the air on a broom-stick or a spit to distant places to attend the meetings of the witches. At these meetings the devil always presided. They were enabled also to transform themselves into various shapes, particularly to assume the forms of cats and hares, in which they most delighted; to inflict diseases on whomsoever they thought proper; and to punish their enemies in a variety of ways.

The belief that certain persons were endowed with supernatural power, and that they were assisted by invisible spirits, is very ancient. The *sagae* of the Romans seem rather to have been sorcerers than witches; indeed the idea of a witch, as above described, could not have been prevalent till after the propagation of Christianity, as the heathens had no knowledge of the Christian *devil*.

Witchcraft was universally believed in Europe till the 16th century, and even maintained its ground with tolerable firmness till the middle of the seventeenth. Vast numbers of reputed witches were convicted and condemned to be burnt every year. The methods of discovering them were various. One was, to weigh the supposed criminal against the church bible, which, if she was guilty, would preponderate: another, by making her attempt to say the Lord's Prayer; this no witch was able to repeat entirely, but would omit some part or sentence thereof. It is remarkable, that all witches did not hesitate at the same place; some leaving out one part, and some another. Teats, through which the imps sucked, were indubitable marks of a witch: these were always raw, and almost insensible; and, if squeezed, sometimes yielded a drop of blood. A witch could not weep more than three tears, and that only out of the left eye. This want of tears was,

Witchcraft was, by the witch-finders, and even by some judges, considered as a very substantial proof of guilt. Swimming a witch was another kind of popular ordeal generally practised: for this she was stripped naked, and cross-bound, the right thumb to the left toe, and the left thumb to the right toe. Thus prepared, she was thrown into a pond or river, in which, if guilty, she could not sink; for having, by her compact with the devil, renounced the benefit of the water of baptism, that element, in its turn, renounced her, and refused to receive her into its bosom. Sir Robert Filmer mentions two others by fire: the first, by burning the thatch of the house of the suspected witch; the other, burning any animal supposed to be bewitched by her, as a hog or ox. These, it was held, would force a witch to confess.

The trial by the stool was another method used for the discovery of witches. It was thus managed: Having taken the suspected witch, she was placed in the middle of a room upon a stool or table, cross-legged, or in some other uneasy posture; to which if she submitted not, she was then bound with cords: there she was watched, and kept without meat or sleep for the space of 24 hours (for, they said, within that time they should see her imp come and suck). A little hole was likewise made in the door for imps to come in at; and lest it should come in some less discernible shape, they that watched were taught to be ever and anon sweeping the room, and, if they saw any spiders or flies, to kill them; if they could not kill them, then they might be sure they were imps. If witches, under examination or torture, would not confess, all their apparel was changed, and every hair of their body shaven off with a sharp razor, lest they should secrete magical charms to prevent their confessing. Witches were most apt to confess on Fridays.

By such trials as these, and by the accusation of children, old women, and fools, were thousands of unhappy women condemned for witchcraft, and burnt at the stake. In the 18th volume of the Statistical Account of Scotland there is the trial of two witches, William Coke and Alison Dick, in Kirkaldy, in 1636. The evidence on which they were condemned is absolutely ridiculous: they were, however, burnt for witchcraft. The expences which the town and kirk-session were put to on this occasion were as follows:

<i>In primis.</i> —To Mr James Miller, when he went to Prestowne for a man to try them, 47 s.	L. 2 7
<i>Item.</i> —To the man of Culros, (the executioner), when he went away the first time, 12 s.	0 12
<i>Item.</i> —For coals for the witches, 24 s.	1 4
<i>Item.</i> —In purchasing the commission,	9 3
<i>Item.</i> —For one to go to Finmouth for the laird to sit upon their assize as judge,	0 6
<i>Item.</i> —For harden to be jumps to them,	3 10
<i>Item.</i> —For making of them,	0 8

Summa for the kirk's part L. 17 10 Scots.

The Town's part of expences debursed extraordinarily upon William Coke and Alison Dick.

<i>In primis.</i> —For ten loads of coals to burn them, 5 merks,	L. 3 6 8
<i>Item.</i> —For a tar barrel, 14 s.	0 14 0
<i>Item.</i> —For towes,	0 6 0
<i>Item.</i> —To him that brought the executioner, 2 18 0	2 18 0
<i>Item.</i> —To the executioner for his pains,	8 14 0
<i>Item.</i> —For his expences here,	0 16 4

Carry over L. 16 15 0

Brought over	L. 16 15 0
<i>Item.</i> —For one to go to Finmouth for the laird,	0 6 0

Summa town part, L. 17 1 Scots
Both, L. 34 11

Or L. 2 17 7 Ster.

For a considerable time after the inquisition was erected, the trials of witches (as heretics) were confined to that tribunal; but the goods of those who were condemned being confiscated to the holy office, its ministers were so active in discovering forcerers, that the different governments found it necessary to deprive them of the cognizance of this crime. On the continent, commissioners were then appointed for the discovery and conviction of witches, who, though less active than the inquisitors, were but too zealous in prosecuting their function. In 1493, Sprenger and Justitor, two persons employed in this commission, published a collection of trials, most of which had come before themselves, under the title of *Malleus Maleficarum*: this served as a kind of institute for their successors.

The first writers against witchcraft were stigmatized as Atheists, though they only endeavoured to prove the imbecility of the persons accused, and the infatuation or the knavery of their accusers. Such were the epithets bestowed by Dr Henry More, and even by Cudworth himself. Wierus, the disciple of the celebrated Azrippa, gave rise to the first great controversy on this subject. His master had taught him humanity; and he endeavoured, but with too feeble a hand, to stop the bloody proceedings of the judges. Wierus appears to have been a well-disposed, weak man, with extensive reading on his subject, but too narrow-minded to comprehend it thoroughly. He involved himself in unspeakable difficulties, by admitting the action of supernatural powers in certain diseases, and in possessions, while he denied that witches had any concurrence in them. These appearances (said he) are illusions of the devil, who persuades simple and melancholy persons that the mischief he himself performs, is done by them, and at their pleasure. He was weak enough to attempt the explanation of every story alleged by his antagonists, without questioning the truth of the facts.

Bodinus, a French lawyer of eminence, who had assisted at several trials of witches, wrote against Wierus, in his *Demonomania*. He urged the concurrent testimonies of sufficient witnesses, and the confessions of the witches themselves, to establish the existence of sorcery. Wierus owned that the unhappy persons believed themselves to be guilty of the crimes alleged against them, but that they were deceived by the devil. But what do you make of the witches meetings, cried Bodinus? The witches (replied his antagonist) are atrabilious. This explanation was so unsatisfactory that Wierus passed for a magician, whom the devil had furnished with specious arguments to save others from punishment. Lerchemer, Godelmann, Ewichius, Ewaldus, and some others, followed him, notwithstanding this stigma; but they were opposed by men of more acuteness and consistency than themselves; by Remigius, who had condemned several hundreds of forcerers to the flames; Delrio, whose book is a complete *Corpus Magicæ*; Cujas, Erastus, Scribonius, Camerarius, and a crowd of others.

In this country, while the belief in witchcraft was supported by royal authority (for James I. is universally known to have written on demonology) countenanced by Bacon, and generally adopted among the people, only one writer was hardy enough to oppose it. This was Reginald Scott, who published a collection of impostures detected, under the title of *Discoveries of Witchcraft*. James ordered the book

Witchcraft

to be burnt by the common executioner, and the judges continued to burn witches as usual. During the civil wars, upwards of eighty were hanged in Suffolk, on the accusations of Hopkins the witch-finder. Webster was the next writer against witchcraft; but he had a different fate from that of Scott, for most of his arguments were refuted by Glanville. This very acute writer was induced to publish his Philosophical Considerations about Witchcraft, by the apprehension, that the increasing disbelief of witches and apparitions tended to affect the evidences of religion, and even of a Deity. - In respect of argument, he was certainly superior to his adversaries; his reasoning is perspicuous, though sometimes subtle, rested on the most specious foundations of evidence, and arranged with great skill.

On the continent, this controversy seemed almost forgotten, till Bekker published his *Monde Enchantée*, in which he denied the existence of witches on the Cartesian principle, that the Deity is the source of all action, consequently actions so opposite to his nature and attributes cannot be supposed to exist. He was answered by Frederick Hoffman, the father of the modern theory and practice of medicine, in his dissertation *De Diaboli Potentia in Corpora*.

The latest witchcraft frenzy was in New England, about 1692, when the execution of witches became a calamity more dreadful than the sword or the pestilence. The accusers became so daring, that neither civil nor religious authority would have proved a security against their attacks, if all the prosecutions had not been suddenly dropped, and the prisoners set at liberty. So far did those wretches proceed in absurdity, that a dog was accused of throwing persons into fits by looking at them. As soon as the prosecutions were stopped, all reports of witchcraft ceased.

It would be ridiculous to attempt a serious refutation of the existence of witches; and at present, luckily, the task is unnecessary. In this country, at least, the discouragement long given to all suspicion of witchcraft, and the repeal of the statutes against that crime, have very much weakened, though perhaps they have not entirely eradicated, the persuasion. On the continent, too, it is evidently on the decline; and notwithstanding the exertions of Dr De Haen, and of the celebrated Lavater, we have little doubt but that in a short time posterity will wonder at the credulity of their ancestors. That there ever were witches, is an opinion that cannot for a moment be believed by a thinking man. The actions imputed to them were either absurd or impossible; the witnesses by whose evidence they were condemned, either weak enthusiasts or downright villains; and the confessions ascribed to the witches themselves, the effects of a disordered imagination produced by cruel treatment and excessive watchings. As to the nightly meetings, demagogues themselves have been obliged to confess, that they were nothing else but uneasy dreams, often produced by soporific compositions. The facts which have been brought forward by the advocates for witchcraft bear in their front the most evident marks of trick and imposture; and this has constantly been found out whenever these facts have been properly examined. See SORCERY.

WITENA MOT, or WITENA Gemot, among the Anglo-Saxons, was a term which literally signified the assembly of the wise men; and was applied to the great council of the nation of latter days called the *parliament*.

WITHERS of a HORSE, the juncture of the shoulder-bones at the bottom of the neck and mane, towards the upper part of the shoulder.

WITNESS, in law, a person who gives evidence in any cause, and is sworn to speak the truth, the whole truth, and nothing but the truth.

Trial by WITNESSES, a species of trial without the inter-

vention of a jury. This is the only method of trial known to the civil law, in which the judge is left to form in his own breast his sentence upon the credit of the witnesses examined: but it is very rarely used in the English law, which prefers the trial by jury before it in almost every instance. Save only that when a widow brings a writ of dower, and the tenant pleads that the husband is not dead; this being looked upon as a dilatory plea, is in favour of the widow, and for greater expedition allowed to be tried by witnesses examined before the judges: and so, saith Finch, shall no other case in our law. But Sir Edward Coke mentions some others; as, to try whether the tenant in a real action was duly summoned, or the validity of a challenge to a juror: so that Finch's observation must be confined to the trial of direct and not collateral issues. And in every case Sir Edward Coke lays it down, that the affirmative must be proved by two witnesses at the least.

WITSIUS (Herman), a learned and eminent divine of North Holland, born at Enckhuysen in 1626. He was professor of divinity successively at Franeker, Utrecht, and Leyden; and applied himself successively to oriental learning, of which his capital work *Aegyptiaca* affords sufficient proof. His Economy of the Covenants between God and Men, is warmly recommended by Mr Hervey in his *Theron* and *Aspasio*. He died in 1708.

WITENBERG, a city of Germany, capital of the circle of Upper Saxony, 50 miles north of Dresden. It is under immediate vassalage, and the seat of an aulic judicatory, a general superintendency, an inspection and consistory. The town is not large; but is well fortified, and contains a famous university, in which Melancthon was a professor. In this place Martin Luther first began to preach against the pope's indulgences; and in the cathedral of All Saints he is said to have been buried. In the old citadel of this town the ancient Saxon electors used to reside. Besides the university, there is a Latin school in the town, with six masters. The library belonging to the university is said to be very valuable. In 1756 the Prussians being masters of the town, destroyed a part of its fortifications. E. Long. 12. 47. N. Lat. 51. 49.

WOAD, in botany. See ISATIS.

The preparation of woad for dying, as practised in France, is minutely described by Aitrac, in his *Memoirs* for a Natural History of Languedoc. The plant puts forth at first five or six upright leaves, about a foot long and six inches broad: when these hang downwards, and turn yellow, they are fit for gathering: five crops are gathered in one year. The leaves are carried directly to a mill, much resembling the oil or tan mills, and ground into a smooth paste. If this process was deferred for some time, they would putrefy, and send forth an insupportable stench. The paste is laid in heaps, pressed close and smooth, and the blackish crust, which forms on the outside, reunited if it happens to crack: if this was neglected, little worms would be produced in the cracks, and the woad would lose a part of its strength. After lying for fifteen days, the heaps are opened, the crust rubbed and mixed with the inside, and the matter formed into oval balls, which are pressed close and solid in wooden moulds. These are dried upon hurdles: in the sun, they turn black on the outside; in a close place, yellowish, especially if the weather be rainy. The dealers in this commodity prefer the first, though it is said the workmen find no considerable difference betwixt the two. The good balls are distinguished by their being weighty, of an agreeable smell, and when rubbed, of a violet colour within. For the use of the dyer, these balls require a farther preparation: they are beat with wooden mallets, on a brick or stone floor, into a gross powder; which is heaped up in
the

Woad
||
Woadhoo.

the middle of the room to the height of four feet, a space being left for passing round the sides. The powder, moistened with water, ferments, grows hot, and throws out a thick fetid fume. It is shovelled backwards and forwards, and moistened every day for twelve days; after which it is stirred less frequently, without watering, and at length made into a heap for the dyer.

Woad not only affords a lasting and substantial blue, which, according to the scale of the dyers, may be reduced into many different shades, but is also of great use in dyeing and fixing many other colours. But notwithstanding this, and its being a commodity of our own, the use of it has very much declined since the introduction of indigo; for the purchase of which large sums go annually out of the nation. The reason of this is, that indigo affords a more lively and pleasing colour, is managed with more ease by the dyers, and does their business more expeditiously. Yet with all these advantages, it is universally acknowledged, that the colour which indigo affords is inferior to that of woad in many respects, and particularly in permanency; for which reason, they are frequently used in conjunction; woad to give solidity and substance, and indigo to give brightness and colour. But the worst consequence that has attended the use of indigo is, not barely lessening the consumption, but abating the price and depreciating the intrinsic value of woad; so that less care is taken in the management of it; to which in a great measure the inferiority of its colour, at least in some places, is at present owing. The declension in its consumption is not the case here only, but also in other countries; for it was once the great staple of Languedoc, and was cultivated also in Normandy, and in other provinces of France; as it also is in Spain, Portugal, the Azores, and Canary islands, Switzerland, in the neighbourhood of Geneva, in different parts of Germany, and in Sweden.

An idea has been entertained, that by an alteration in the manner of curing of it, the inconveniencies that are supposed to attend the use of it might be removed, and that woad might be brought to answer all the purposes of indigo; which, if it could be accomplished, would be most certainly a great advantage, and an advantage which every true lover of his country would wish should take place here rather than any where else. The author of the Natural History of Languedoc suggests, that woad, if cured in the same manner as indigo, might produce as lively a colour; and adds, that from some experiments made by himself, he is convinced the method would effectually answer. The celebrated M. Du Hamel du Monceau informs us, that having proposed to Mr Fontenelle, a physician in Louisiana, the cultivating the pastel there in the manner of indigo, that gentleman acquainted him, that by treating indigo after the manner of pastel, he had obtained a very beautiful green: which indeed is always the case when the indigo is only allowed to absorb a small quantity of oxygen; for it is now well known that its blue colour is owing to the absorption of that gas.

WOAHOO, one of the Sandwich Islands, lying to the north-west of Morotoi, at the distance of seven leagues. From the appearance of the north-east and north-west parts, it is the finest island of the group. Nothing can exceed the verdure of the hills, the variety of wood and lawn, and rich cultivated valleys, which the whole face of the country displays. A bay is formed by the north and west extremities, into which a fine river empties itself, through a deep valley; but as the water is brackish for 200 yards from the entrance, watering in it is not convenient. It contains about 60,000 inhabitants. Lieutenant Hergest, commander of the *Dædalus* storeship, who had been sent from England,

in 1791, to New South Wales, and thence to the Southern Pacific Ocean, with a supply of provisions for the Discovery sloop, Captain Vancouver, then on a voyage of discovery, was here surprised and murdered by the natives, together with Mr Gooch, the astronomer. W. Long. 157. 51. N. Lat. 21. 43.

WODEN. See ODIN, and MYTHOLOGY, n^o 40.

WODEVILLE (Anthony), earl of Rivers, brother to the queen of Edward IV. was born in the end of 1442, or in the beginning of 1443. Though one of the most accomplished men of his age, very little is known of his private history. He was early and constantly employed either in the tumults of those turbulent times, or in discharging the duties of some of the highest offices of the state, with which he was invested. Yet he found leisure to cultivate letters, and to be the author of works which, though of little value now, made some noise in that age, when learning was at a low ebb in England. These consisted chiefly of translations from the French; and his Lordship, with his printer Caxton, were the first English writers who had the pleasure to see their works published from the press. This accomplished, brave, and amiable nobleman was treacherously imprisoned by Richard III. in Pomfret castle, where, during his confinement, he composed a short poem, which has been preserved by John Rous of Warwick, and breathes, says Dr Henry, a noble spirit of pious resignation to his approaching fate. He was beheaded on the 23d of June 1483, in the 41st year of his age.

WOLAW, a town in Germany, in Silesia, and capital of a duchy of the same name. It is surrounded with strong walls and a moat, and one part of the houses are built with stone. The castle is also encompassed with deep ditches, and the greatest part of the inhabitants are employed in a woollen manufactory. In 1709 a Protestant church was allowed to be built here. It is seated on the river Oder, 20 miles north-west of Breslau, and 32 south east of Glogau. E. Long. 16. 54. N. Lat. 51. 18.

WOLD, WELD, or DYERS *Woad*. See RESEDA.

WOLF, in zoology. See CANIS.

Wolf-Fish, or *Sea-Wolf*. See ANARCHICAS.

WOLF or *Woolf Poison*. See POISON.

WOLFE (Major-general James), was born at Westerham in the county of Kent, about the beginning of the year 1726. His father was Lieutenant-general Edward Wolfe. He went into the army when very young; and applying himself with unwearied assiduity to the study of his profession, soon became remarkable for his knowledge and his genius. He distinguished himself at the battle of Lafelt when little more than 20, and received the highest encomiums from the commander in chief. After the peace he still continued to cultivate the art of war. He contrived to introduce the greatest regularity and the exactest discipline into his corps, and at the same time to preserve the affection of every soldier. In 1758 he was present as a brigadier-general at the siege of Louisbourg. He landed first on the island at the head of his division; and in spite of the violence of the surf, and the force and well directed fire of the enemy, drove them from their post with great precipitation. The surrender of the town, which happened soon after, was in a great measure owing to his activity, bravery, and skill. The fame which he acquired during this siege pointed him out to Mr Pitt, who was then minister, as the properest person to command the army destined to attack Quebec. This was the most difficult and the most arduous undertaking of the whole war. Quebec was the capital of the French dominions in North America; it was well fortified, situated in the midst of an hostile country, and defended by an army of 20,000 men, regulars and militia, besides a considerable

derable number of Indian allies. The troops destined for his expedition consisted of ten battalions, making up altogether about 7000 men. Such was the army destined to oppose three times their own number, defended by fortifications, in a country altogether unknown, and in a late season of that climate for military operations. But this little army, says an officer who was present at that expedition, and who has been so obliging as to communicate all the information he desired, was always sanguine of success; for they were commanded by General Wolfe, who, by a very uncommon magnanimity and nobleness of behaviour, had attached the troops so much to his person, and inspired them with such resolution and steadiness in the execution of their duty, that nothing seemed too difficult for them to accomplish. The admirable skill with which his measures were planned, and the prudence and vigour with which they were executed, is well known. He landed his army on the northern shore of the river St Lawrence in spite of the enemy, and forced them to a battle, in which they were completely defeated. The consequence of this battle was the reduction of Quebec, and the conquest of Canada. In the beginning of the battle General Wolfe was wounded in the wrist by a musket-ball: he wrapt his handkerchief round it, continued to give his orders with his usual calmness and perspicuity, and informed the soldiers that the advanced parties on the front had his orders to retire, and that they needed not be surprised when it happened. Towards the end of the battle he received a new wound in the breast; he immediately retired behind the rear-rank supported by a grenadier, and laid himself down on the ground. Soon after a shout was heard; and one of the officers who stood by him exclaimed, "See how they run!" The dying hero asked with some motion, "Who run?" "The enemy (replied the officer); they give way every where." The general then said, "Pray, do one of you run to Colonel Burton, and tell him to march Webb's regiment with all speed down to Charles River, to cut off the retreat of the fugitives from the bridge. Now, God be praised, I shall die happy!" He then turned on his side, closed his eyes, and expired.

The death of General Wolfe was a national loss universally lamented. He inherited from nature an animating fervour of sentiment, an intuitive perception, an extensive capacity, and a passion for glory, which stimulated him to acquire every species of military knowledge that study could comprehend, that actual service could illustrate and confirm. This noble warmth of disposition seldom fails to call forth and unfold all the liberal virtues of the soul. Brave above all estimation of danger; generous, gentle, complacent, and humane; the pattern of the officer, the darling of the soldier. There was a sublimity in his genius which soared above the pitch of ordinary minds; and had his faculties been exercised to their full extent by opportunity and action, had his judgment been fully matured by age and experience, he would, without doubt, have rivalled in reputation the most celebrated captains of antiquity. His body was brought to England, and buried with military honours in Westminster abbey, where a magnificent monument is erected to his memory.

WOLFE (Christian), a celebrated German philosopher, was born at Breslau in 1679. After having been well instructed in the rudiments of learning and science in his own country, Wolfe prosecuted his studies successively in the universities of Jena, Hamburgh, and Leipzig. At the age of 26 he had acquired so much distinction, that he was appointed professor of mathematics, and soon afterwards of philosophy in general, in the university of Hall. After Leibnitz had published his *Theodicea*, Wolfe, struck with the novelty of the edifice which that philosopher had raised,

assiduously laboured in the investigation of new metaphysical truths. He also digested the Elements of Mathematics in a new method, and attempted an improvement of the art of reasoning in a treatise On the Powers of the Human Understanding. Upon the foundation of Leibnitz's doctrine of Monads, he formed a new system of Cosmology and Pneumatology, digested and demonstrated in a mathematical method. This work, entitled *Thoughts on God, the World, and the Human Soul*, was published in the year 1719; to which were added, in a subsequent edition, *Heads of Ethics and Policy*.

Wolfe was now rising towards the summit of philosophical reputation, when the opinion which he entertained on the doctrine of necessity being deemed by his colleagues inimical to religion, and an oration which he delivered in praise of the morality of the Chinese having given much offence, an accusation of heresy was publicly brought against him; and, though he attempted to justify himself in a treatise which he wrote on the subject of fatality, a royal mandate was issued in November 1723, requiring him to leave the Prussian dominions. Having been formerly invited by the landgrave of Hesse-Cassel to fill a professor's chair in the university of Cassel, Wolfe now put himself under the patronage of that prince, who had the liberality to afford him a secure asylum, and appointed him professor of mathematics and philosophy. The question concerning the grounds of the censure which had been passed upon Wolfe was now every where freely canvassed; almost every German university was inflamed with disputes on the subject of liberty and necessity; and the names of Wolfians and Anti Wolfians were every where heard. After an interval of nine years, the king of Prussia reversed his sentence of exile, and appointed him vice-chancellor of the university of Hall; where his return was welcomed with every expression of triumph. From this time he was employed in completing his Institutes of Philosophy, which he lived to accomplish in every branch except policy. In 1745 he was created a baron by the elector of Bavaria, and succeeded Ludowig in the office of chancellor of the university. He continued to enjoy these honours till the year 1754, when he expired. He possessed a clear and methodical understanding; which by long exercise in mathematical investigations was particularly fitted for the employment of digesting the several branches of knowledge into regular systems; and his fertile powers of invention enabled him to enrich almost every field of science in which he laboured, with some valuable additions. The lucid order which appears in all his writings enables his reader to follow his conceptions with ease and certainty, through the longest trains of reasoning.

WOLFEMBTLE, a considerable town of Germany, in the circle of Lower Saxony, and duchy of Brunswick, with a castle where the duke of Brunswick Wolfembuttle resides. It is one of the strongest places in Germany, though the fortifications want repairing in several places. There is an excellent library, kept in a building lately erected for that purpose, consisting of 116,000 printed books, and 2000 uncommon books, with a cabinet of curiosities, relating to natural history. It is seated on the river Ocker, five miles south of Brunswick, and 30 west of Halberstadt. E. Long. 10. 42. N. Lat. 52. 18.

WOLFRAM, or TUNGSTEN. See TUNGSTEN.

WOLFRAM, in natural history and chemistry, the name of a peculiar mineral, lately ranged among the semi-metals. See MINERALOGY. p. 134, col. 2.

This mineral, which the Germans have called *wolfram* or *Wolfenbuttle's wolfrath*, a name translated into Latin *spuma lupi*, or rather *Mineralogy lupus Jovis*, has been met with hitherto only in mines of tin; translated by *Allegheum*, it is *vol. II.*

Wolfram.

is an error owing to their confounding some glossy iron-ores with the true wolfram, as appears by the specimens which are frequently found in cabinets under this name. It has been, on account of the bad effects produced by this mineral in the smelting of tin-ores, from which it is very difficult to separate it by washing, because of its great specific weight, that the names of *spuma lupi*, *lupus Fovis*, and *wolfram*, have been given to it by the miners and smelters.

This is really a metallic ore, and contains the very semi-metal lately discovered in the tungsten; both being mineralized, or rather formed by the same tungstenic acid.

1. It is of a black or brown shining colour, of a radiated or foliated texture, of a moderate hardness, and sometimes so brittle as to be easily broken between the fingers; but it is very weighty, its specific gravity being = 7,119.

2. When scratched it shows a red trace, and this distinguishes it from the tungsten, MINERALOGY, part ii. p. 73. col. 1: which is a variety of the ore of the same semi-metal.

3. It is found in scattered masses, crystallized into hexædral flat prisms, coming to a point, with four sides, and these points terminated obliquely.

4. Internally it is shining, with the lustre almost of a metal.

5. When it is broken, its texture appears leafy; and the leaves are flat, but somewhat confused.

6. On some sides they are unequal, and very seldom striated.

7. It is always opaque; and when scraped, it yields a powder of a dark reddish grey.

8. The wolfram will not melt by itself with the blow-pipe, the angles being only rounded; but,

9. Internally it preserves its structure and colour without change.

10. With microcosmic salt (*phosphate of ammoniac*) it fuses with effervescence; and forms a glass of a pale red in the exterior flame, and much darker in the interior.

11. With borax it likewise effervesces, and forms by the interior flame a glass of a greenish yellow, which by the exterior turns reddish.

12. Being exposed in a crucible to a strong fire for one hour, it swelled, became spongy, and of a brownish colour; entered into a semi-vitrification; and was attracted by the magnet.

13. Equal parts of nitre and wolfram being put in a red-hot crucible, they detonated, or rather boiled up with a blue flame round the edges, and a nitrous vapour arose; the matter, when cold, on being put into water, partly dissolved; and a few drops of acid produced a white precipitation.

14. Pounded wolfram, digested in a sand heat with a sufficient quantity of marine acid, to the depth of the thickness of a finger above the matter, after one hour's boiling, the powder turned yellow; which is the same phenomenon as happens with the tungstenic acid. See CHEMISTRY-Index.

15. It appears by the chemical analysis of wolfram made by Mess. John and Faust de Luyart, that its contents consist of 22 parts of manganese in the state of black oxyd; 13,5 of iron, 65 of a yellow wolfranic oxyd, and of quartz and tin.

16. A good quantity of this yellow oxyd being collected, it was observed that it was entirely insipid, and that its specific gravity was = 6,120. It effervesces with microcosmic salt; produces a transparent blue colour without any shade of red; and effervesces also with borax and with mineral alkali. This same matter does not dissolve in water; but when triturated with it, forms a kind of emulsion; to which the acetous acid gives a blue colour, but does not dissolve it.

This matter, however, dissolves completely in caustic vegetable alkali, both by the dry and moist way; and the liquor acquires a great bitterness. By pouring on it some nitrous acid a precipitate ensues, which leaves on the filtre a white salt; and this being welledulcorated, has a taste at first sweet, afterwards sharp and bitter, producing a very disagreeable sensation on the throat. It is in fact a true acid combined with a portion of the alkali and precipitating acid.

17. This acid melts, if alone, by the flame urged with the blow-pipe.

18. This white salt is a true metallic triple salt, as appears by putting 100 grains in a crucible with powdered charcoal; for after one hour and a half of a strong fire, when cooled a button was found, which fell to powder between the fingers. Its colour was brown; and, on examining it with a magnifier, there was a congeries of metallic globules, of the bigness of pins heads; which, when broken, exhibit the metallic appearance of a steel colour in the fracture; and their specific gravity was = 17,600.

19. These metallic globules, melted with other metals, gold and platina excepted, afford ductile alloys with silver or copper; and hard ones with cast iron, tin, antimony, bismuth, and manganese.

It has been supposed that this is a new metal before unknown: That this was evinced, 1. by its specific gravity, equal to 17,600; 2. by the tinges it gives to different glasses; 3. by its great difficulty to fuse, which is greater than that of manganese; 4. by the yellow colour of its calx; 5. its alloys with other metals; 6. its insolubility, at least by a direct method, with mineral acids; 7. its easy solution in alkalis; 8. the emulsion it gives with water; 9. and by the blue colour it gives to acetous acid. We are not certain, however, how far this opinion has been corroborated by later experiments.

WOLFSPERG, a town of Germany, in Lower Carinthia, with a castle, on which the district about it depends, which is 20 miles in length, and 10 in breadth. It is seated on the river Lavand, at the foot of a mountain covered with wood, and full of wolves, from whence the town took its name. It is 36 miles east of Clagenfurt. E. Long. 15. o. N. Lat. 46. 56.

WOLGAST, a pretty considerable town of Germany, in the circle of Upper Saxony, and in Pomerania, capital of a territory of the same name, with a castle, and one of the best and largest harbours on the Baltic Sea. It is a well-built place, subject to Sweden, and seated on the river Pän. E. Long. 14.4. N. Lat. 54. 1.

WOLLASTON (William), descended of an ancient family in Staffordshire, was born in 1659. He was in 1674 admitted a pensioner in Sidney college, Cambridge, where, notwithstanding several disadvantages, he acquired a great degree of reputation. In 1682, seeing no prospect of preferment, he became assistant to the head master of Birmingham school. Some time after, he got a small lecture about two miles distant, but did the duty the whole Sunday; which, together with the business of a great free-school for about four years, began to break his constitution. During this space he likewise underwent a great deal of trouble and uneasiness, in order to extricate two of his brothers from some inconveniences, to which their own imprudence had subjected them. In 1688 affairs took a new turn. He found himself by a cousin's will intitled to a very ample estate; and came to London that same year, where he settled; choosing a private, retired, and studious life. Not long before his death, he published his treatise, intitled *The Religion of Nature Delineated*; a work for which so great a demand was made, that more than 10,000 were sold in a very few years. He had scarcely completed the publication

cation of it, when he unfortunately broke an arm; and this adding strength to distempers that had been growing upon him for some time, accelerated his death; which happened upon the 29th of October 1724. He was a tender, humane, and in all respects worthy man; but is represented to have had something of the irascible in his constitution and temperament. His Religion of Nature Delineated exposed him to some censure, as if he had put a slight upon Christianity by laying so much stress, as he does in this work, upon the obligations of truth, reason, and virtue; and by making no mention of revealed religion. But this censure must have been the offspring of ignorance or envy, since it appears from the introduction to his work, that he intended to treat of revealed religion in a second part, which he lived not to finish.

WOLSEY (Thomas), a famous cardinal and archbishop of York, is said to have been the son of a butcher at Ipswich. He studied at Magdalen college, Oxford, where he became acquainted with the learned Erasmus; and in the year 1500 became rector of Lymington in Somersetshire: he was afterwards made chaplain to king Henry VIII. and obtained several preferments. Having gradually acquired an entire ascendancy over the mind of Henry VIII. he successively obtained several bishoprics, and at length was made archbishop of York, lord high-chancellor of England, and prime minister; and was for several years the arbiter of Europe. Pope Leo X. created him cardinal in 1515, and made him *legatè à latere*; and the emperor Charles V. and the French king Francis I. loaded him with favours, in order to gain him over to their interest: but after having first sided with the emperor, he deserted him to espouse the interest of France. As his revenues were immense, his pride and ostentation were carried to the greatest height. He had 500 servants; among whom were 9 or 10 lords, 15 knights, and 40 esquires. His ambition to be pope, his pride, his exactions, and his political delay of Henry's divorce, occasioned his disgrace. In the earlier part of his life he seems to have been licentious in his manners; for there goes a story, that soon after his preferment to the living of Lymington in Somersetshire, he was put into the stocks by Sir Amias Paulet, a neighbouring justice of the peace, for getting drunk and making a riot at a fair. This treatment Wolsey did not forget when he arrived at the high station of lord-chancellor of England; but summoned his corrector up to London, and, after a severe reprimand, enjoined him six years close confinement in the Temple. Whatever may have been his faults, there can be no doubt of their having been aggravated both by the zealous reformers and by the creatures of Henry VIII. who was himself neither Papist nor Protestant; for there is every reason to believe that the cardinal was sincere in his religion; and sincerity, or at least consistency, was then a crime. Wolsey was the patron of learned men; a judge and munificent encourager of the polite arts; and ought to be considered as the founder of Christ-church college, Oxford; where, as well as in other places, many remains of his magnificent ideas in architecture still exist. He died in 1530.

WOMAN, the female of the human species. See HOMO.

WOMB, or UTERUS. See ANATOMY, n^o 108.

WOOD (Anthony), an eminent biographer and antiquarian, was the son of Thomas Wood, bachelor of arts and of the civil law, and was born at Oxford in 1632. He studied at Merton college, and in 1655 took the degree of master of arts. He wrote, 1. The History and Antiquities

of the University of Oxford; which was afterwards translated into Latin by Mr Wase and Mr Peers, under the title of *Historia & Antiquitates Universitatis Oxoniensis*, 2 vols folio. 2. *Athenæ Oxonienses*; or an exact Account of all the Writers and Bishops who have had their Education in the University of Oxford, from the Year 1500 to 1600, 2 vols folio; which was greatly enlarged in a second edition published in 1721 by bishop Tanner. Upon the first publication of this work the author was attacked by the university, in defence of Edward earl of Clarendon, lord high chancellor of England, and chancellor of the university, and was likewise animadverted upon by bishop Burnet; upon which he published a Vindication of the Historiographer of the University of Oxford. He died at Oxford of a retention of urine in 1695.

WOOD, a substance whereof the trunks and branches of trees consist. It is composed of a number of concentric circles or zones, one of which is formed every year; consequently their number corresponds to the age of the tree. These zones vary in thickness according to the degree of vegetation that took place the year of their formation. They are also of different degrees of thickness in different parts, that part of the tree which is most exposed to the sun and best sheltered growing tallest; hence in this country that part of the zone which looked towards the south while the tree was growing is generally thickest. The innermost circle or zone is the one which was first formed, the outermost was formed the year before the tree was cut down. These zones are at first very soft and tender, and harden by degrees as the tree becomes older: this is the reason that the middle of a tree is so often much better wood than the outside of it.

The proper ligneous part of the wood consists of longitudinal fibres, disposed in fasciculi, and possessed of considerable hardness. It is this longitudinal direction of the fibres that renders it so much easier to cleave wood lengthwise than across the tree or in any other direction. See PLANT.

Chemists have attempted to ascertain the ingredients which enter into the composition of wood. The task, however, is so difficult, that they have by no means made the same progress that they have done in analysing the various mineral productions of nature. When wood is distilled, water comes over first; soon after it begins to be impregnated with oil, then an empyreumatic oil comes over, then carbonic acid gas, then hydrogen gas, and lastly carbonated hydrogen gas: a coal remains behind, which is composed of charcoal, fixed alkali, various earths, and sometimes also of several neutral salts and metallic substances. This was once looked upon by chemists as a perfect analysis, and it was supposed that all the various substances above-mentioned existed in plants in their proper form. But this is now known to be a mistake: the action of the fire produces new combinations in the ultimate ingredients of the plant, and thus produces new substances; and it is only these that are obtained by the above process. It is sufficient however to show, that wood is composed in a great measure of carbon, oxygen, and hydrogen, combined variously and in unknown proportions with one another; as most of the products of the distillation can be retolved into these substances.

There are many varieties of wood possessed of distinguishing properties, as cedar, box, ebony, &c. See these articles.

For the *Method of Staining or Dyeing Wood*, see TURNING.

For more complete information concerning wood, see also PLANT, TREE, *STRENGTH of Materials*.

Fossil Wood. Fossil wood, or whole trees, or parts of them, are very frequently found buried in the earth, and that in different strata; sometimes in stone, but more usually

Word. in earth; and sometimes in small pieces loose among gravel. These, according to the time they have lain in the earth, or the matter they have lain among, are found differently altered from their original state; some of them having suffered very little change; and others being so highly impregnated with crystalline, sparry, pyritical, or other extraneous matter, as to appear mere masses of stone, or lumps of the common matter of the pyrites, &c. of the dimensions, and, more or less, of the internal figure of the vegetable bodies into the pores of which they have made their way.

The fossil woods which we find at this day are, according to these differences, arranged by Dr Hill into three kinds; 1. The less altered: 2. The pyritical: and, 3. The petrified.

Of the trees, or parts of them, less altered from their original state, the greatest store is found in digging to small depths in bogs, and among what is called *peat* or *turf earth*, a substance used in many parts of the kingdom for fuel. In digging among this, usually very near the surface, immense quantities of vegetable matter of various kinds are found buried; in some places there are whole trees scarce altered, except in colour; the oaks in particular being usually turned to a jetty black; the pines and firs, which are also very frequent, are less altered, and are as inflammable as ever, and often contain between the bark and wood a black resin. Large parts of trees have also been not infrequently met with unaltered in beds of another kind, and at much greater depths, as in the strata of clay and loam, among gravel, and sometimes even in solid stone.

Beside these harder parts of trees, there are frequently found also in the peat earth vast quantities of the leaves and fruit and catkins of the hazel and similar trees: these are usually mixed with sedge and roots of grass, and are scarce at all altered from their usual texture. The most common of these are hazel nuts; but there are frequently found also the twigs and leaves of the white poplar; and a little deeper usually there lies a cracked and shattered wood, the crevices of which are full of a bituminous black matter: and among this the stones of plums and other stone-fruits are sometimes found, but more rarely.

In this state the fruits and larger parts of trees are usually found: what we find of them more altered, are sometimes large and long, sometimes smaller and shorter branches of trees, sometimes small fragments of branches, and more frequently small shapeless pieces of wood. The larger and longer branches are usually found bedded in the strata of stone, and are more or less altered into the nature of the stratum they lie in. The shorter and smaller branches are found in vast variety in the strata of blue clay used for making tiles in the neighbourhood of London. These are prodigiously plentiful in all the clay-pits of this kind, and usually carry the whole external resemblance of what they once were, but nothing of the inner structure; their pores being wholly filled, and undistinguishably closed, by the matter of the common pyrites, so as to appear mere simple masses of that matter. These fall to pieces on being long exposed to moisture; and are so impregnated with vitriol that they are what is principally used for making the green vitriol or copperas at Deptford and other places.

The irregular masses or fragments of petrified wood are principally of oak, and are most usually found among gravel; though sometimes in other strata. These are variously altered by the insinuation of crystalline and stony particles; and make a very beautiful figure when cut and polished, as they usually keep the regular grain of the wood, and show exactly the several circles which mark the different years growth. These, according to the different matter which

has filled their pores, assume various colours, and the appearance of the various fossils that have impregnated them; some are perfectly white, and but moderately hard; others of a brownish black, or perfectly black, and much harder; others of a reddish black, others yellowish, and others greyish, and some of a ferruginous colour. They are of different weights also and hardneses, according to the nature and quantity of the stony particles they contain: of these some pieces have been found with every pore filled with pure pellucid crystal; and others in large masses, part of which is wholly petrified and seems mere stone, while the rest is crumbly and is unaltered wood. That this alteration is made in wood, even at this time, is also abundantly proved by the instances of wood being put into the hollows of mines, as props and supports to the roofs, which is found after a number of years as truly petrified as that which is dug up from the natural strata of the earth. In the pieces of petrified wood found in Germany, there are frequently veins of spar or of pure crystal, sometimes of earthy substances, and often of the matter of the common pebbles: these fragments of wood sometimes have the appearance of parts of the branches of trees in their natural state, but more frequently they resemble pieces of broken boards; these are usually capable of a high and elegant polish.

Many substances, it is certain, have been preserved in the cabinets of collectors, under the title of *petrified wood*, which have very little right to that name. But where the whole outer figure of the wood, the exact lineaments of the bark, or the fibrous and fistular texture of the stræ, and the vestiges of the utriculi and trachææ or air-vessels, are yet remaining, and the several circles yet visible which denoted the several years growth of the tree, none can deny these substances to be real fossil wood. See PETRIFICATION.

Composition for preserving Wood. See CHEMISTRY, n^o 621 and 700.

WOOD (*sylva*), in geography, a multitude of trees extended over a large continued track of land, and propagated without culture. The generality of woods only consist of trees of one kind.—The ancient Saxons had such a veneration for woods, that they made them sanctuaries.—It is ordained, that none shall destroy any wood, by turning it into tillage or pasture, &c. where there are two acres or more in quantity, on pain of forfeiting 40s. an acre, by 35 Henry VIII. c. 17. All woods that are felled at 14 years growth, are to be preserved from destruction for eight years; and no cattle put into the ground till five years after the felling thereof, &c. 13 Eliz. c. 25. The burning of woods or underwood is declared to be felony; also those persons that maliciously cut or spoil timber-trees, or any fruit-trees, &c. shall be sent to the house of correction, there to be kept three months, and whipt once a month.

WOODSTOCK, a town of Oxfordshire, in England, pleasantly seated on a rising ground, and on a rivulet; a well compacted borough-town, and sends two members to parliament; but is chiefly noted for Blenheim-house, a fine palace, built in memory of the victory obtained by the duke of Marlborough over the French and Bavarians in August 1704. It was erected at the public expence, and is one of the noblest seats in Europe. One of the passages to it is over a bridge with one arch, 190 feet in diameter, resembling the Rialto at Venice. The gardens take up 100 acres of ground; and the offices, which are very grand, have room enough to accommodate 300 people. The apartments

ments of the palace are magnificently furnished; and the staircases, statues, paintings, and tapestry, surprisngly fine. The town is about half a mile from the palace, having several good inns; and a manufacture of steel chains for watches, and excellent gloves. It is 8 miles north of Oxford, and 60 west-north-west of London. W. Long. 1. 15. N. Lat. 51. 52.

WOODWARD (Dr John), was born in 1665, and educated at a country school, where he learned the Latin and Greek languages, and was afterwards sent to London, where he is said to have been put apprentice to a linen-draper. He was not long in that station, till he became acquainted with Dr Peter Barwick, an eminent physician, who took him under his tuition and into his family. Here he prosecuted with great vigour and success the study of philosophy, anatomy, and physic. In 1692, Dr Stillingfleet quitting the place of professor of physic in Gresham college, our author was chosen to succeed him, and the year following was elected F. R. S. In 1695 he obtained the degree of M. D. by patent from archbishop Tension; and the same year he published his *Essay toward a Natural History of the Earth*. He afterward wrote many other pieces, which have been well received by the learned world. He founded a lecture in the university of Cambridge, to be read there upon his *Essay*, &c. and handsomely endowed it. He died in 1728.

WOOF, among manufacturers, the threads which the weavers shoot across with an instrument called the *shuttle*. See CLOTH.

WOOKEY or *OKRY Hole*, a remarkable cavern two miles from the city of Wells in Somersetshire; for an account of which, see the article GROTTTO.

WOOL, the covering of sheep. See OVIS, and SHEEP.

Wool resembles hair in a great many particulars; but besides its fineness, which constitutes an obvious difference, there are other particulars which may serve also to distinguish them from one another. Wool, like the hair of horses, cattle, and most other animals, completes its growth in a year, and then falls off as hair does, and is succeeded by a fresh crop. It differs from hair, however, in the uniformity of its growth, and the regularity of its shedding. Every filament of wool seems to keep exact pace with another in the same part of the body of the animal; the whole crop springs up at once; the whole advances uniformly together; the whole loosens from the skin nearly at the same period, and thus falls off if not previously shorn, leaving the animal covered with a short coat of young wool, which in its turn undergoes the same regular mutations.

Hairs are commonly of the same thickness in every part; but wool constantly varies in thickness in different parts, being generally thickest at the points than at the roots. That part of the fleece of sheep which grows during the winter is finer than what grows in summer. This was first observed by Dr Anderson, the editor of the *Bee*, and published in his *Observations on the Means of exciting a Spirit of National Industry*.

While the wool remains in the state it was first shorn off the sheep's back, and not sorted into its different kinds, it is called *fleece*. Each fleece consists of wool of divers qualities and degrees of fineness, which the dealers therein take care to separate. The French and English usually separate each fleece into three sorts, *viz.* 1. Mother-wool, which is that of the back and neck. 2. The wool of the tails and legs. 3. That of the breast and under the belly. The Spaniards make the like division into three sorts, which they call *prime*, *second*, and *third*; and for the greater ease, denote each bale or pack with a capital letter, denoting the sort. If the triage or separation be well made, in 15 bales

there will be 12 marked R, that is, refine, or prime; two marked F, for fine, or second; and one S, for thirds.

The wools most esteemed are the English, chiefly those about Leominster, Cotswold, and the Isle of Wight; the Spanish, principally those about Segovia; and the French, about Berry: which last are said to have this peculiar property, that they will knot or bind with any other sort; whereas the rest will only knot with their own kind.

Among the ancients, the wools of Attica, Megara, Laodicea, Apulia, and especially those of Laurentum, Parma, and Altino, were the most valued. Varro assures us, that the people there used to clothe their sheep with skins, to secure the wool from being damaged.

Of late a great deal of attention has been paid to wool in this country, as well as several others. Several very spirited attempts have been made to improve it, by introducing superior breeds of sheep, and better methods of managing them. For this purpose has been formed the *British Wool Society*.

British Wool Society, an association formed for the purpose of obtaining the best breeds of fine-woolled sheep, with a view of ascertaining, by actual experiments, how far each species or variety is calculated for the climate of Great Britain; the qualities of their wool respectively; the uses to which each kind of wool could be most profitably employed in different manufactures; and the comparative value of each species of sheep, so far as the same can be determined.

Attention had for some time been paid by the Highland Society to a famous breed of fine-woolled sheep in Shetland; but it occurred to Sir John Sinclair of Ulbster, baronet, and to Dr James Anderson, well known as the author of many useful publications, that the improvement of British wool was a matter of too much importance to be entrusted to a society which is obliged to devote its attention to such a variety of objects as the general improvement of the Highlands of Scotland. The latter of these gentlemen, therefore, in an Appendix to the Report of the Committee of the Highland Society of Scotland, for the year 1792, proposed the plan of a *patriotic association for the improvement of British wool*; and the former, who was convened of the committee to whom the subject of Shetland wool had been referred, wrote circular letters, recommending the plan. The consequence of which was, that, on the 31st of January 1791, several noblemen and gentlemen of the highest respectability met in Edinburgh, and constituted themselves into a *Society for the Improvement of British Wool*. Of this society Sir John Sinclair was elected president; after which, in an excellent speech, he pointed out to the members the objects of the institution, the means by which those objects could be attained, and the advantages which would result from their united labours. This address was afterwards printed by order of the society.

The particular breeds of sheep to which the society proposed to direct its attention, were sheep for the hilly parts of Scotland; sheep for the plains, or the Lowland breed; and sheep for the islands. They were to try experiments also with sheep from foreign countries, distinguished by any particular property.

The principal objects which the members had in view, during the first year of their association, were, 1. To collect specimens of the best breeds which Great Britain at that period afforded, in order to ascertain the degree of perfection to which sheep had already been brought in this kingdom. 2. To procure from every country, distinguished for the quality of its sheep and wool, specimens of the different breeds it possessed, in order to ascertain how far the original breed, or a mixed breed from it and the native

Wookey. sheep of the country, could thrive in Scotland. 3. To disperse as much as possible all these breeds, both foreign and domestic, over the whole kingdom, wherever proper persons could be found to take charge of them, in order to try experiments on a more extensive scale than the society itself could do; to spread information, and to excite a spirit for the improvement of sheep and wool in every part of the country.

Sir John Sinclair had previously collected a flock, consisting of sheep of the Spanish, Herefordshire, Southdown, Cheviot, Lomond hills, and Shetland breeds, and of a mixed breed from these different sheep. This flock amounted to 110 rams, ewes, and lambs. M. D'Aubenton, in consequence of a correspondence with Sir John Sinclair, sent over to the society ten rams and five ewes, of real Spanish breed, which had been originally intrusted to his care by the late king of France: these, after encountering a number of obstacles, and after being stopped and threatened to be slaughtered at the customhouse of BRIGHTLANTON for the use of the poor, arrived safe at Leith. Lord Sheffield, at the same time, sent to the society four rams and six ewes of the Southdown and Spanish breeds. Mr Dighton of Killall, in Shropshire, presented them with three Hereford rams, reckoned by many the best breed in England; the society at the same time ordered 150 ewes of the same breed, and two ewes of the Long Mountain breed, reckoned the best in Wales, to be sent along with them. They purchased 57 rams and 173 ewes of the Cheviot breed, reckoned the best in Scotland, for the hilly parts of the country. Lord Daer sent them 20 ewes of an excellent breed, which existed at Moelrum in Galloway. The late earl of Oxford sent them in a present three rams of the Norfolk crossed by the Cape of Good Hope breed. Mr Isaac Grant junior of Leghorn, in conjunction with Mr Sibbald merchant at Leith, presented them an Apulian ram and ewe; the ram arrived in safety, but the ewe unfortunately died on the passage. Mr Baron Seton of Preston, in Linlithgowshire, sent them a ram and two ewes of a Spanish breed, which had been for some time kept in Sweden unmixed with any other. They purchased 100 ewes of a small breed existing in the parish of Leuchars in Fife, much resembling the Shetland. The Right Honourable William Conynghame of Ireland sent them 11 Spanish rams, 7 Spanish ewes, 10 three-fourth breed and 16 one-half breed Spanish and Irish ewes. Lord Sheffield sent them 8 rams and 18 ewes; and his Majesty made them a present of two rams.

Thus, in the course of one year, the society acquired by donation or purchase about 800 sheep of different sorts and ages, and many of them from foreign countries: about 500 of these were distributed over different parts of Scotland, the greater number of which were sold to gentlemen anxious to promote the views of the society, and well qualified to make experiments on the different breeds which they had obtained. The greatest part of the remainder were taken by different gentlemen who kept them for the society, and according to their directions, without any expence.

It is impossible to produce an instance of so much having been accomplished by a society of private individuals in so short a time. Nor was this all; the same year Mr Andrew Kerr, a very intelligent sheep-farmer on the borders of England, was sent, at the expence of the society, to examine the state of sheep-farming along the east coast of Scotland and the interior parts of the Highlands. His tour was printed by order of the society, and contains the first intimation of the possibility of the Cheviot breed thriving in the north of Scotland.

In the year 1792, Messrs Redhead, Laing, and Marshall,

were sent by the society, to make a survey of the state of sheep-farming through some of the principal counties of England; the result of which was also published by the society, and contains more information on the subject of the different breeds of England than any work hitherto published; and in 1794, Mr John Naismyth was sent on a tour through the southern districts of Scotland, which completed the circuit of almost the whole kingdom.

Thus a few private individuals, unaided by the public purse, had boldness enough to undertake ascertaining the comparative value of the different kinds of sheep in their own country, and to introduce some of the most celebrated breeds of other countries, and succeeded in the spirited attempt. It is impossible in this place to state more minutely the various other transactions of the society; to enter into any detail of the premiums given by this respectable institution for the improvement of the celebrated Shetland breed; or to explain how, as if it were by magic, in a country where the manufacture of wool was little known, articles manufactured of that material were made, rivalling, and in some cases surpassing, the most celebrated fabrics of other countries. A war having unfortunately arisen, it became impossible to pay the same attention, or to carry on with the same success, novel enterprizes; even old establishments often fall a sacrifice amidst the horrors of war. The utmost that the British Wool Society could expect to do, was to preserve the institution in such a state, that when peace shall be happily restored it may revive with double energy and spirit.

WOOLSTON (Thomas), an English divine, was born at Northampton in 1669, and educated at Cambridge. His first appearance in the learned world was in 1705, in a work intitled, *The old Apology for the Truth of the Christian Religion, against the Jews and Gentiles*, revived. He afterward wrote many pieces: but what made the most noise, were his *Six Discourses on the Miracles of Christ*; which occasioned a great number of books and pamphlets upon the subject, and raised a prosecution against him. At his trial in Guildhall, before the lord chief-justice Raymond, he spoke several times himself; and urged, that "he thought it very hard that he should be tried by a set of men who, though otherwise very learned and worthy persons, were no more judges of the subjects on which he wrote, than himself was a judge of the most crabbed points of the law." He was sentenced to a year's imprisonment, and to pay a fine of 100*l*. He purchased the liberty or the rules of the King's bench, where he continued after the expiration of the year, being unable to pay the fine. The greatest obstruction to his deliverance from confinement was, the obligation of giving security not to offend by any future writings, he being resolved to write again as freely as before. Whilst some supposed that this author wrote with the settled intention of subverting Christianity under the pretence of defending it, others believed him disordered in his mind; and many circumstances concurred which gave countenance to this opinion. He died, January 27. 1732-3, after an illness of four days; and, a few minutes before his death, uttered these words: "This is a struggle which all men must go through, and which I bear not only patiently, but with willingness." His body was interred in St George's church-yard, Southwark.

WOOLWICH, a town in Kent, with a market on Fridays, but no fair. It is seated on the river Thames, and of great note for its fine docks and yards, where men of war are built; as also for its vast magazines of great-guns, mortars, bombs, cannon-balls, powder, and other warlike stores. It has likewise an academy, where the mathematics are taught, and young officers instructed in the military art.

It is nine miles east of London. E. Long. 0. 10. N. Lat. 51. 30.

WORCESTER, in Latin *Wigornia*, the capital of a county of England of the same name, stands on the river Severn, but so low that it can hardly be seen till one is close upon it. It is supposed to be the Branonium of Antoninus, the Branogenium of Ptolemy, and to have been built by the Romans to awe the Britons on the other side of the Severn. It was made an episcopal see about the year 680 by Sexulphus bishop of the Mercians; but the present cathedral was begun by Wulfston in the year 1084. The town hath been several times burnt down: first, in 1041, by Hardicanute, who also massacred the citizens; secondly, not long after William Rufus's time; and a third time, when king Stephen besieged and took it. Here, in latter times, was fought that battle, in which Charles II. with his Scots army, was defeated by Cromwell. In a garden, near the south gate of the city, where the action was hottest, the bones of the slain are often dug up. It had formerly strong walls and a castle; but these have been demolished long ago. It is now a large city, the streets broad and well paved, and some of them very regular and well built, particularly Foregate-street; so that in general it is a very agreeable place. The cathedral is a stately edifice, and among other monuments in it are those of king John, of Arthur, elder brother to Henry VIII. and of the countess of Salisbury, who gave occasion to the institution of the order of the Garter. There are seven or eight hospitals in and about the city; of which that built and endowed by Robert Berkley of Sperchley, Esq; is a very noble one. There is a school founded by Henry VIII. three other schools, and six charity-schools. The Guildhall and the workhouse are stately structures. The churches, St Nicholas and All-Saints, have been lately rebuilt, and are very handsome edifices. The city carries on a great trade; for which it is chiefly indebted to its situation upon the Severn. A prodigious number of people are employed in and about it in the manufacture of broad-cloth and gloves. The Welch inhabit a part of it, and speak their own language. Its market is well supplied with provisions, corn, and cattle, and its quay is much frequented by ships. By a charter from James I. it is governed by a mayor, six aldermen, who are justices of the peace, and chosen out of 24 capital citizens; a sheriff, the city being a county of itself; a common council, consisting of 48 other citizens, out of which two chamberlains are yearly chosen, a recorder, town-clerk, two coroners, a sword-bearer, 13 constables, and four sergeants at mace. Of the bishops of this see, there have been, it is said, one pope, four saints, seven lord high-chancellors, 11 archbishops, two lord treasurers, one chancellor to the queen, one lord president of Wales, and one vice president. The city at present gives title of earl and marquis to the duke of Beaufort. W. Long. 1. 55. N. Lat 52. 10.

WORCESTER (earl of). See TIPTOTT.

WORCESTERSHIRE, a county of England, bounded by Warwickshire on the east, by Gloucestershire on the south, by the counties of Hereford and Salop on the west, and on the north by Staffordshire. According to Templeman, it is 36 miles in length, 28 in breadth, and about 130 in circumference, within which it contains seven hundreds, and a part of two others, 11 market towns, of which three are boroughs, one city, namely *Worcester*, 152 parishes, about 540,000 acres, and 103,000 inhabitants.

This being an inland county, well cultivated, and free from lakes, marshes, or stagnant waters, the air is very sweet and wholesome all over it. The soil in general is very rich, producing corn, fruit, especially pears, of which they make

a great deal of perry; hops, and pasture. The hills are covered with sheep, and the meadows with cattle. Hence they have wool, cloth, stuffs, butter, and cheese in abundance. They are also well supplied with fuel, either wood or coal, and salt from their brine pits and salt springs. Of the last they have not only enough for themselves, but export large quantities by the Severn; which noble river, to the great convenience and emolument of the inhabitants, runs from north to south through the very middle of the country, enriching the soil, and yielding it plenty of fish, and an easy expeditious conveyance of goods to and from it. The other rivers by which it is watered are the Stour, Avon, Teme, &c. It sends nine members to parliament, viz. two for the county, two for the city of Worcester, two for Droitwich, two for Evesham, and one for Bewdley; and lies in the diocese of Worcester, and Oxford circuit.

WORD, in language, an articulate sound designed to represent some idea or notion. See GRAMMAR and LANGUAGE. See also LOGIC, Part I. chap. 1.

WORD, or *Watch-Word*, in military affairs, is some peculiar word or sentence, by which the soldiers know and distinguish one another in the night, &c. and by which spies and designing persons are discovered. It is used also to prevent surprisings. The word is given out in an army every night to the lieutenant, or major-general of the day, who gives it to the majors of the brigades, and they to the adjutants; who give it first to the field-officers, and afterwards to a serjeant of each company, who carry it to the subalterns. In garrisons it is given after the gate is shut to the town major, who gives it to the adjutants, and they to the serjeants.

Words of Command. See EXERCISE and MANUAL.

Signals by the Drum, made use of in exercising of the Army, instead of the Word of Command, viz.

<i>Signals by the drum.</i>	<i>Operations.</i>
<i>A short roll,</i>	To caution.
<i>A flum,</i>	To perform any distinct thing.
<i>To arms,</i>	To form the line or battalion.
<i>The march,</i>	To advance, except when intended for a salute.
<i>The quick march,</i>	To advance quick.
<i>The point of war,</i>	To march and charge.
<i>The retreat,</i>	To retreat.
<i>Drum ceasing,</i>	To halt.
<i>Two short rolls,</i>	To perform the flank firing.
<i>The dragoon march,</i>	To open the battalion.
<i>The grenadier march,</i>	To form the column.
<i>The troop,</i>	To double divisions.
<i>The long roll,</i>	To form the square.
<i>The grenadier march,</i>	To reduce the square to the column.
<i>The preparative,</i>	To make ready and fire.
<i>The general</i>	To cease firing.
<i>Two long rolls,</i>	To bring or lodge the colours.

WORK, in the manege. To work a horse, is to exercise him at pace, trot, or gallop, and ride him at the manege. To work a horse upon volts, or head and haunches in or between two heels, is to passage him, or make him go sidewise upon parallel lines.

To *Work*, in sea language, is to direct the movements of a ship, by adapting the sails to the force and direction of the wind. See SEAMANSHIP.

Work, Carpenters, Clock, Crown, Field, Fire, Fret, Grotesque, Horn, Mosaic. See the several articles, together with FORTIFICATION and PYROTECHNEY.

Work-House, a place where indigent, vagrant, and idle people, are set to work, and supplied with food and clothing.

Work-house.

Work-houses are of two kinds, or at least are employed for two different purposes. Some are used as prisons for vagrants or sturdy beggars, who are there confined and compelled to labour for the benefit of the society which maintains them; whilst others, sometimes called *poor-houses*, are charitable asylums for such indigent persons as through age or infirmity are unable to support themselves by their own labour. The former kind of work house, when under proper management, may be made to serve the best of purposes; of the latter we are acquainted with none which entirely commands our approbation.

To make confinement in a work-house operate to the correction of vagrants and disorderly persons (and if it produce not this effect it can hardly be considered as a beneficial institution), the prisoners should be shut up in separate cells, and compelled to labour for their own subsistence. A crew of thieves and vagabonds associating with each other is a hell upon earth, in which every individual is hardened in his crimes by the countenance and conversation of his companions; and wretches who, when at liberty, choose to beg or steal rather than to earn a comfortable livelihood by honest industry, will submit to any punishment which a humane overseer can inflict rather than work for the benefit of others. No punishment indeed will compel a vagrant to labour. He may assume the appearance of it, but he will make no progress; and the pretext of sickness or weakness is ever at hand for an excuse. Hence it is that thieves and strumpets are too often dismissed from work-houses and bridewells ten times more the children of the devil than when they entered them.

To remedy these evils, we can think of no better method than to confine each prisoner in a cell by himself, and to furnish him daily with such an allowance of bread and water as may preserve him from *immediate* death; for the only compulsion to make such men work seriously is the fear of want, and the only way to reform them is to leave them to their own meditations on the consequences of their past conduct. There are surely very few persons, if any, whose aversion from labour would not be conquered by the pinchings of hunger and the certain prospect of perishing by famine; and it is to be hoped that there are not many so totally divested of every latent principle of virtue as not to be brought by such solitude to a due sense of their former wickedness. Should one or two, however, be occasionally found so very obdurate as to suffer themselves to perish rather than work, their deaths would prove a salutary beacon to others, and their blood would be on their own heads; for we have the express command of St Paul himself, that "if any will not work, neither should he eat."

No doubt it would be proper that the meditations of vagabonds confined in a work-house should be directed by the private admonitions of a pious and intelligent clergyman; but it is not every clergyman who is qualified to discharge such a duty. If he be actuated by a zeal not according to knowledge, or if he have not with equal care studied human nature and the word of God, his admonitions will be more likely to provoke the profane ridicule of his auditor, and harden him in his wickedness, than to excite in his breast such sorrow for his sins as shall "bring forth fruits meet for repentance." To render the instruction of thieves and vagrants of any use, it must be accurately adapted to the case of each individual; and however excellent it may be in itself, it will not be listened to unless offered at seasons of uncommon seriousness, which the instructor should therefore carefully observe.

That such wholesome severity as this would often reform the inhabitants of work-houses, appears extremely probable from the effects of a similar treatment of common prostitutes

mentioned by Lord Kames in his *Sketches of the History of Man*: "A number of those wretches were in Edinburgh confined in a house of correction, on a daily allowance of threepence, of which part was embezzled by the servants of the house. Pinching hunger did not reform their manners; for being absolutely idle, they encouraged each other in vice, waiting impatiently for the hour of deliverance. Mr Stirling the superintendent, with the consent of the magistrates, removed them to a clean house; and instead of money, appointed for each a pound of oat-meal daily, with salt, water, and fire for cooking. Relieved now from distress, they longed for comfort. What would they not give for milk or ale? Work (says he) will procure you plenty. To some who offered to spin, he gave flax and wheels, engaging to pay them half the price of their yarn, retaining the other half for the materials furnished. The spinners earned about ninepence weekly; a comfortable addition to what they had before. The rest undertook to spin, one after another; and before the end of the first quarter they were all of them intent upon work. It was a branch of his plan to set free such as merited that favour; and some of them appeared to be so thoroughly reformed as to be in no danger of a relapse."

Work-houses erected as charitable asylums appear to us, in every view that we can take of them, as institutions which can serve no good purpose. Economy is the great motive which inclines people to this mode of providing for the poor. There is comparatively but a very small number of mankind in any country so aged and infirm as not to be able to contribute, in some degree, to their subsistence by their own labour; and in such houses it is thought that proper work may be provided for them, so that the public shall have nothing to give in charity but what the poor are absolutely unable to procure for themselves. It is imagined likewise, that numbers collected at a common table, can be maintained at less expence than in separate houses; and foot soldiers are given for an example, who could not live on their pay if they did not meet together. But the cases are not parallel. "Soldiers having the management of their pay, can club for a bit of meat; but as the inhabitants of a poor-house are maintained by the public, the same quantity of provisions must be allotted to each. The consequence is what might be expected: the bulk of them reserve part of their victuals for purchasing ale or spirits. It is vain to expect work from them: poor wretches void of shame will never work seriously, where the profit accrues to the public, not to themselves. Hunger is the only effectual means for compelling such persons to work.*"

The poor, therefore, should be supported in their own houses; and to support them properly, the first thing to be done is, to estimate what each can earn by his own labour; for as far only as that falls short of maintenance is there room for charity. In repairing those evils which society did not or could not prevent, it ought to be careful not to counteract the wise purposes of nature, nor to do more than to give the poor a fair chance to work for themselves. The present distress must be relieved, the sick and the aged provided for; but the children must be instructed; and labour, not alms, offered to those who have some ability to work, however small that ability may be. They will be as industrious as possible, because they work for themselves; and a weekly sum of charity under their own management will turn to better account than in a poor-house under the direction of mercenaries. Not a penny of it will be laid out on fermented liquors, unless perhaps as a medicine in sickness. Nor does such low fair call for pity to those who can afford no better. Ale makes no part of the maintenance of those who, in many parts of Scotland,

* Kam Sketches

Scotland, live by the sweat of their brows; and yet the person who should banish all from a charity work-house, would be exclaimed against as hard-hearted, and even void of humanity.

That such a mode of supporting the poor in their own houses is practicable, will hardly admit of a dispute; for it has been actually put in practice in the city of Hamburg ever since the year 1788. At that period such revenues as had till then been expended in alms by the several church-wardens, and those of which the administration had been connected with the work-house, were united under one administration with such sums as were collected from private benevolence. The city was divided into sixty districts, containing each an equal number of poor; and over these 180 overseers were appointed. Actual relief was the first object; but at the very moment that this provision was secured, measures were taken to prevent any man from receiving a shilling which he could have been able to earn for himself. By methods, which our limits will not permit us to state, the overseers were able to make a calculation tolerably exact of what each pauper wanted for bare subsistence, in addition to the fruits of his own labour. A flax-yarn-spinning manufacture was established, in which the yarn is paid for, not by its weight, but by its measure. The clean flax is sold to the poor at a low price, and a certain measure of yarn again bought from them at 30 per cent. above the usual price; so that the overseers are sure that all the yarn spun by the poor will be brought into their office. Every pauper brings with him a book in which the quantity delivered is carefully noted down, which furnishes the overseers with a continual average of the state of industry among their poor.

As soon as this institution was established, the overseers went through their districts, and asked, in all such mansions as could be supposed to harbour want, if the inhabitants stood in need of support? The question to all such poor as wished for relief, and were able to spin, was, Whether they did earn by their work 1s. 6d. a-week? for experience had taught the inhabitants of Hamburg, that many poor live upon that sum; and they knew enough of their poor to suppose, that 1s. 6d. avowed earning was equal to something more. If the answer was affirmative, the pauper stood not in need of weekly assistance. If it was negative, work was given him, which, by being paid 30 per cent. above its value, afforded him 1s. 6d. a-week easily, if he was even an indifferent hand. The far more frequent cases were partial inability by age, or weakness, or want of skill. For poor of the latter description a school was opened, and in three months time the business was easily learnt. During that time, the pauper got first 2s. a-week, and every week afterwards 2d. less, till in the twelfth week he got nothing at all but his earnings, and was dismissed, with a wheel and a pound of flax gratis.

The quantity of work which disabled poor were capable of doing in a week was easily and accurately ascertained by a week's trial in the spinning-school. The result was produced weekly before appointed members of the committee, and the sum which the poor could earn was noted down in their small books. The overseer was directed to pay them weekly what their earnings fell short of 1s. 6d. in every such week, when it appeared from their books that they had earned to the known extent of their abilities. From that moment applications became less frequent; and the committee had an infallible standard for distinguishing real want: for whenever the pauper, if in health (if not, he was peculiarly provided for), had not earned what he could, then he had either been lazy, or had found more lucrative

work; in either case, he was not entitled to a relief for that week, whatever he might be for the following.

Water-works.

This mode of providing for the poor, which attracted the notice and obtained the eulogium of the minister in the British house of commons, has for six years been in Hamburg attended with the happiest consequences. In the streets of that city a beggar is rarely to be seen, whilst those, who stand in need of the charitable contributions of the rich, are much more comfortably, as well as at much less expense, maintained at home, with their children about them, than they could be in work-houses, under the management of mercenary overseers. For a fuller account of this judicious institution, we must refer the reader to Vought's *Account of the Management of the Poor in Hamburg, since the year 1788, in a letter to some friends of the poor in Gr. Britain.*

WATER-WORKS. Under this name may be comprehended almost every hydraulic structure or contrivance; such as, canals, conduits, locks, mills, water-engines, &c. But they may be conveniently arranged under two general heads, 1st, Works which have for their object the conducting, raising, or otherwise managing, of water; and, 2^{dly}, Works which derive their efficacy from the impulse or other action of water. The *first* class comprehends the methods of simply conducting water in aqueducts or in pipes for the supply of domestic consumption or the working of machinery: It comprehends also the methods of procuring the supplies necessary for these purposes, by means of pumps, water, or fire engines. It also comprehends the subsequent management of the water thus conducted, whether in order to make the proper distribution of it according to the demand, or to employ it for the purpose of navigation, by lockage, or other contrivances—And in the prosecution of these things many subordinate problems will occur, in which practice will derive great advantages from a scientific acquaintance with the subject. The *second* class of water-works is of much greater variety, comprehending almost every kind of hydraulic machine; and would of itself fill volumes. Many of these have already occurred in various articles of this Dictionary. In describing or treating them, we have tacitly referred the discussion of their general principles, in which they all resemble each other, to some article where they could be taken in a connected body, susceptible of general scientific discussion, independent of the circumstances which of necessity introduced the particular modifications required by the uses to which the structures were to be applied. That part of the present article, therefore, which embraces these common principles, will chiefly relate to the theory of water-mills, or rather of water-wheels; because, when the necessary motion is given to the axis of the water-wheel, this may be set to the performance of any task whatever.

CLASS I.

1. *Of the conducting of Water.*

THIS is undoubtedly a business of great importance, and makes a principal part of the practice of the civil engineer: It is also a business so imperfectly understood, that we believe that very few engineers can venture to say, with tolerable precision, what will be the quantity of water which his work will convey, or what plan and dimensions of conduit will convey the quantity which may be proposed. For proof of this we shall only refer our readers to the facts mentioned in the article RIVERS, n^o 27, &c.

In that article we have given a sort of history of the progress of our knowledge in hydraulics, a branch of mechanical philosophy which seems to have been entirely unknown

Water-works.

to the ancients. Even Archimedes, the author of almost all that we know in hydrostatics, seems to have been entirely ignorant of any principles by which he could determine the motion of water. The mechanical science of the ancients seems to have reached no farther than the doctrine of equilibrium among bodies at rest. Guglielmini first ventured to consider the motion of water in open canals and in rivers. Its motion in pipes had been partially considered in detached scraps by others, but not so as to make a body of doctrine. Sir Isaac Newton first endeavoured to render hydraulics susceptible of mathematical demonstration: But his fundamental proposition has not yet been freed from very serious objections; nor have the attempts of his successors, such as the Bernoullis, Euler, D'Almbert, and others, been much more successful: so that hydraulics may still be considered as very imperfect, and the general conclusions which we are accustomed to receive as fundamental propositions are not much better than matters of observation, little supported by principle, and therefore requiring the most scrupulous caution in the application of them to any hitherto untried case. When experiments are multiplied so as to include as great a variety of cases as possible; and when these are cleared of extraneous circumstances, and properly arranged, we must receive the conclusions drawn from them as the general laws of hydraulics. The experiments of the Abbé Bossut, narrated in his *Hydrodynamique*, are of the greatest value, having been made in the cases of most general frequency, and being made with great care. The greatest service, however, has been done by the chevalier Buat, who saw the folly of attempting to deduce an accurate theory from any principles that we have as yet learned, and the necessity of adhering to such a theory as could be deduced from experiment alone, independent of any more general principles. Such a theory must be a just one, if the experiments are really general, unaffected by the particular circumstances of the case, and if the classes of experiment are sufficiently comprehensive to include all the cases which occur in the most important practical questions. Some principle was necessary, however, for connecting these experiments. The sufficiency of this principle was not easily ascertained. M. Buat's way of establishing this was judicious. If the principle is ill-founded, the results of its combination in cases of actual experiments must be irregular; but if experiments, seemingly very unlike, and in a vast variety of dissimilar cases, give a train of results which is extremely regular and consistent, we may presume that the principle, which in this manner harmonizes and reconciles things so unlike, is founded in the nature of things; and if this principle be such as is agreeable to our clearest notions of the internal mechanism of the motions of fluids, our presumption approaches to conviction.

Proceeding in this way, the chevalier Buat has collected a prodigious number of facts, comprehending almost every case of the motion of fluids. He first classed them accord-

ing to their resemblance in some one particular, and observed the differences which accompanied their differences in other circumstances; and by considering what could produce these differences, he obtained general rules, deduced from fact, by which these differences could be made to fall into a regular series. He then arranged all the experiments under some other circumstance of resemblance, and pursued the same method; and by following this out, he has produced a general proposition, which applies to the whole of this numerous list of experiments with a precision far exceeding our utmost hopes. This proposition is contained in n^o 59. of the article RIVERS, and is there offered as one of the most valuable results of modern science.

We must, however, observe, that of this list of experiments there is a very large class, which is not direct, but requires a good deal of reflection to enable us to draw a confident conclusion; and this is in cases which are very frequent and important, *viz.* where the declivity is exceedingly small, as in open canals and rivers. The experiments were of the following forms: Two large cisterns were made to communicate with each other by means of a pipe. The surfaces of the water in these cisterns were made to differ only by a small fraction of an inch: and it is supposed that the motion in the communicating pipe will be the same as in a very long pipe, or an open canal, having this very minute declivity. We have no difficulty in admitting the conclusion; but we have seen it contested, and it is by no means intuitive. We had hopes that ere now this important case would have been determined by direct experiments, which the writer of this article was commissioned to make by the Board for Encouraging Improvements and Manufactures in Scotland: But this has been prevented hitherto by his want of health; and we cannot expect that it will be accomplished before the close of this Work. This, however, need not occasion any hesitation in the adoption of M. Buat's general proposition, because the experiments which we are now criticising fall in precisely with the general train of the rest, and show no *general* deviation which would indicate a fallacy in principle.

We apprehend it to be quite unnecessary to add much to what has been already delivered on the motion of waters in an open canal. Their *general progressive* motion, and consequently the quantity delivered by an aqueduct of any slope and dimension, are sufficiently determined; and all that is wanted is the tables which we promised in n^o 65. of the article RIVERS, by which any person who understands common arithmetic may, in five minutes time or less, compute the quantity of water which will be delivered by the aqueduct, canal, conduit, or pipe; for the theorem in n^o 59. of this article applies to them all without distinction. We therefore take this opportunity of inserting these tables, which have been computed on purpose for this Work with great labour.

TABLE

TABLE I. *Logarithms of the Values of the Numerator of the Fraction $\frac{307(\sqrt{d}-0,1)}{\sqrt{d}-L\sqrt{d+1,6}}$ for every Value of the Hydraulic mean D. pib d: Also the Values of $0,3(\sqrt{d}-0,1)$.*

TABLE I. consists of three columns.—*Column 1.* entitled *d*, contains the hydraulic mean depths of any conduit in inches. This is set down for every 10th of an inch in the first 10 inches, that the answers may be more accurately obtained for pipes, the mean depth of which seldom exceeds three or four inches. The column is continued to 100 inches, which is fully equal to the hydraulic mean depth of any canal.

Column 2. contains the logarithms of the values of $\sqrt{d}-0,1$, multiplied by 307; that is, the logarithm of the numerator of the fraction $\frac{307(\sqrt{d}-0,1)}{\sqrt{s}-1, \sqrt{s}+1,6}$ in n° 65. of the article RIVERS.

Column 3. contains the products of the values of $\sqrt{d}-0,1$ multiplied by 0,3.

TABLE II. consists of two columns.—*Column 1.* entitled *s*, contains the denominator of the fraction expressing the slope or declivity of any pipe or canal; that is, the quotient of its length divided by the elevation of one extremity above the other. Thus, if a canal of one mile in length be three feet higher at one end than the other, then *s* is $\frac{5280}{3} = 1760$.

Column 2. contains the logarithms of the denominators of the above mentioned fraction, or of the different values of the quantity $\sqrt{s}-1, \sqrt{s}+1,6$.

These quantities were computed true to the third decimal place. Notwithstanding this, the last figure in about a dozen of the first logarithms of each table is not absolutely certain to the nearest unit. But this cannot produce an error of 1 in 100,000.

Examples of the Use of these Tables.

Example 1. Water is brought into the city of Edinburgh in several mains. One of these is a pipe of five inches diameter. The length of the pipe is 14,637 feet; and the reservoir at Comiston is 44 feet higher than the reservoir into which it delivers the water on the Castle Hill. *Query*, The number of Scotch pints which this pipe should deliver in a minute?

1. We have $d = \frac{5}{4} = 1,25$ inches. The logarithm corresponding to this *d*, being nearly the mean between the logarithms corresponding to 1,2 and 1,3, is 2.49472.

2. We have $s = \frac{14637}{44}$, or 332,7. The logarithm corresponding to this in Table II. is had by taking proportional parts for the difference between the logarithms for $s = 320$ and $s = 340$, and is 1.18533.

3. From 2.49472
Take 1.18533
Remains 1.30939, the logarithm of 20,385 inches.

4. In column 3. of Table I. opposite to $d = 1,2$ and $d = 1,3$ are 0,3 and 0,31, of which the mean is 0,305 inches, the correction for viscosity.

5. Therefore the velocity in inches per second is 20,385 — 0,305, or 20,08.

6. To obtain the Scotch pints per minute (each containing 103,4 cubic inches), multiply the velocity by 60, and this product by 5², and this by 0,7854 (the area of a circle whose diameter is 1), and divide by 103,4. Or, by logarithms,

Add the log. of 20,08	-	1.30276
log. of 60 ²	-	1.77815
log. of 5 ² or 25	-	1.39794
log. of 0,7854	-	9.89509
Carry over		4.37394

Brought over	4.37394	Water-work,
Subtract the log. of 103,4	-	2.01451
Remains the log. of 228,8 pints	-	2.35043

Example 2. The canal mentioned in the article RIVERS, n° 63. was 18 feet broad at the surface, and 7 feet at the bottom. It was 4 feet deep, and had a declivity of 4 inches in a mile. *Query*, The mean velocity?

1. The slant side of the canal, corresponding to 4 feet deep and 5² projection, is 6,8 feet; therefore the border touched by the water is 6,8 + 7 + 6,8, = 20,6. The area is $4 \times \frac{18+7}{2} = 50$ square feet. Therefore $d =$

$\frac{50}{20,6} = 2,427$ feet, or 29,124 inches. The logarithm corresponding to this in Table I. is 3.21112, and the correction for viscosity from the third column of the same Table is 1,58.

2. The slope is one-third of a foot in a mile, or one foot in three miles. Therefore *s* is 15,840. The logarithm corresponding to this is 2.03280.

3. From	3.21113
Subtract	2.08280
Remains	1.12833 = log. of 13,438 inches.
Subtract for viscosity	- 1.58
Velocity per second	11,858

This velocity is considerably smaller than what was observed by Mr Watt. And indeed we observe, that in the very small declivities of rivers and canals, the formula is a little different. We have made several comparisons with a formula which is essentially the same with Buat's, and comes nearer in these cases. Instead of taking the hyperbolic logarithm of $\sqrt{s}+1,6$, multiply its common logarithm by 2², or multiply it by 9, and divide the product by 4; and this process is vastly easier than taking the hyperbolic logarithm.

We have not, however, presumed to calculate tables on the authority of our own observations, thinking too respectfully of this gentleman's labours and observations. But this subject will, ere long, be fully established on a series of observations on canals of various dimensions and declivities, made by several eminent engineers during the execution of them. Fortunately Mr Buat's formula is chiefly founded on observations on small canals; and is therefore most accurate in such works where it is most necessary, viz. in mill courses, and other derivations for working machinery.

We now proceed to take notice of a few circumstances which deserve attention, in the construction of canals, in addition to those delivered in the article RIVERS.

When a canal or aqueduct is brought off from a basin or larger stream, it ought always to be widened at the entry, if it is intended for drawing off a continued stream of water: For such a canal has a slope, without which it can have no current. Suppose it filled to a dead level to the farther end. Take away the bar, and the water immediately begins to flow off at that end. But it is some time before any motion is perceived at the head of the canal, during all which time the motion of the water is augmenting in every part of the canal; consequently the slope is increasing in every part, this being the sole cause of its stream. When the water at the entry begins to move, the slope is scarcely sensible there; but it sensibly deepens every moment with the increase of velocity, which at last attains its maximum relative to the slope and dimensions of the whole canal; and this regulates the depth of water in every point down the stream. When all has attained a state of permanency, the slope at the entry remains much greater than in any other part

Water-works.

part of the canal: for this slope must be such as will produce a velocity sufficient for supplying its TRAIN.

And it must be remembered, that the velocity which must be produced greatly exceeds the mean velocity corresponding to the train of the canal. Suppose that this is 25 inches. There must be a velocity of 30 inches at the surface, as appears by the Table in the article RIVERS, n^o 80. This must be produced by a real fall at the entry.

In every other part the slope is sufficient, if it merely serves to give the water (already in motion) force enough for overcoming the friction and other resistances. But at the entry the water is stagnant, if in a basin, or it is moving past laterally, if the aqueduct is derived from a river; and, having no velocity whatever in the direction of the canal, it must derive it from its slope. The water therefore which has acquired a permanent form in such an aqueduct, must necessarily take that form which exactly performs the offices requisite in its different portions. The surface remains horizontal in the basin, as at KC (fig. 1.), till it comes near the entry of the canal AB, and there it acquires the form of an undulated curve CDE; and then the surface acquires an uniform slope EF, in the lower part of the canal, where the water is in train.

If this is a drain, the discharge is much less than might be produced by the same bed if this sudden slope could be avoided. If it is to be navigated, having only a very gentle slope in its whole length, this sudden slope is a very great imperfection, both by diminishing the depth of water, which might otherwise be obtained along the canal, and by rendering the passage of boats into the basin very difficult, and the coming out very hazardous.

All this may be avoided, and the velocity at the entry may be kept equal to that which forms the train of the canal, by the simple process of enlarging the entry. Suppose that the water could accelerate along the slopes of the canal, as a heavy body would do on a finely polished plane. If we now make the width of the entry in its different parts inversely proportional to the fictitious velocities in those parts, it is plain that the slope of the surface will be made parallel to that of the canal which is in train. This will require a form somewhat like a bell or speaking-trumpet, as may easily be shown by a mathematical discussion. It would, however, be so much evaded at the basin as to occupy much room, and it would be very expensive to make such an excavation. But we may, at a very moderate expence of money and room, make the increase of velocity at the entry almost insensible. This should always be done, and it is not all expence: for if it be not done, the water will undermine the banks on each side, because it is moving very swiftly, and will make an excavation for itself, leaving all the mud in the canal below. We may observe this enlargement at the entry of all natural derivations from a basin or lake. It is a very instructive experiment, to fill up this enlargement, continuing the parallel sides of the drain quite to the side of the lake. We shall immediately observe the water grow shallower in the drain, and its performance will diminish. Supposing the ditch carried on with parallel sides quite to the side of the basin, if we build two walls or dykes from the extremities of those sides, bending outwards with a proper curvature (and this will often be less costly than widening the drain), the discharge will be greatly increased. We have seen instances where it was nearly doubled.

The enlargement at the mouths of rivers is generally owing to the same cause. The tide of flood up the river produces a superficial slope opposite to that of the river, and

this widens the mouth. This is most remarkable when the tides are high, and the river has little slope.

After this great fall at the entry of a canal, in which all the filaments are much accelerated, and the inferior ones most of all, things take a contrary turn. The water, by rubbing on the bottom and the sides, is retarded; and therefore the section must, from being shallow, become a little deeper, and the surface will be convex for some distance till all comes into train. When this is established, the filaments nearest the bottom and side are moving slowest, and the surface (in the middle especially) retains the greatest velocity, gliding over the rest. The velocity in the canal, and the depth of the section, adjust themselves in such a manner that the difference between the surface of the basin and the surface of the uniform section of the canal corresponds exactly to the velocity. Thus, if this be observed to be two feet in a second, the difference of height will be $\frac{1}{8}$ th of an inch.

All the practical questions that are of considerable importance respecting the motion of water in aqueducts, may be easily, though not elegantly, solved by means of the tables.

But it is to be remembered, that these tables relate only to uniform motion, that is, to water that is in train, and where the velocity suffers no change by lengthening the conduit, provided the slope remain the same. It is much more difficult to determine what will be the velocity, &c. in a canal of which nothing is given but the form, and slope, and depth of the entry, without saying how deep the water runs in it. And it is here that the common doctrines of hydraulics are most in fault, and unable to teach us how deep the water will run in a canal, though the depth of the basin at the entry be perfectly known. Between the part of the canal which is in train and the basin, there is an interval where the water is in a state of acceleration, and is afterwards retarded.

The determination of the motions in this interval is exceedingly difficult, even in a rectangular canal. It was one great aim of Mr Buat's experiments to ascertain this by measuring accurately the depth of the water. But he found that when the slope was but a very few inches in the whole length of his canal, it was not in train for want of greater length; and when the slope was still less, the small fractions of an inch, by which he was to judge of the variation of depth, could not be measured with sufficient accuracy. It would be a most desirable point to determine the length of a canal, whose slope and other dimensions are given, which will bring it into train; and what is the ratio which will then obtain between the depth at the entry and the depth which will be maintained. Till this be done, the engineer cannot ascertain by a direct process what quantity of water will be drawn off from a reservoir by a given canal. But as yet this is out of our reach. Experiments, however, are in view which will promote the investigation.

But this and similar questions are of such importance, that we cannot be said to have improved hydraulics, unless we can give a tolerably precise answer. This we can do by a sort of retrograde process, proceeding on the principles of uniform motion established by the Chevalier Buat. We may suppose a train maintained in the canal, and then examine whether this train can be produced by any fall that is possible at the entry. If it can, we may be certain that it is so produced, and our problem is solved.

We shall now point out the methods of answering some chief questions of this kind.

Quest. 1. Given the slope s and the breadth w of a canal, and the height H of the surface of the water in the basin above the bottom of the entry, to find the depth h and

Plate
DXLI.W
W
V

and velocity V of the stream, and the quantity of water Q which is discharged?

The chief difficulty is to find the depth of the stream where it is in train. For this end, we may simplify the hydraulic theorem of uniform motion in n° 59. of the article

RIVER; making $V = \frac{\sqrt{N} \cdot d}{\sqrt{S}}$, where g is the velocity (in

inches) acquired in a second by falling, d is the hydraulic mean depth, and \sqrt{S} stands for $\sqrt{S - L \sqrt{S+1,5}}$. N is

a number to be fixed by experiment (see RIVER. n° 53.) depending on the contraction or obstruction sustained at the entry of the canal, and it may in most common cases be taken

as 244 ; so that $\sqrt{N} \cdot g$ may be somewhat less than 307 . To find it, we may begin by taking for our depth of stream a quantity b , somewhat smaller than H the height of the surface of the basin above the bottom of the canal.

With this depth, and the known width w of the canal, we can find the hydraulic depth d (RIVER, n° 48). Then with

\sqrt{d} and the slope find V by the Table: make this $V = \frac{\sqrt{N} \cdot g \cdot d}{\sqrt{S}}$.

This gives $\sqrt{N} \cdot g = \frac{V \cdot \sqrt{S}}{\sqrt{d}}$. This value of $N \cdot g$ is sufficiently exact; for a small error of depth hardly affects the hydraulic mean depth.

After this preparation, the expression of the mean velocity in the canal will be $\frac{\sqrt{N} \cdot g \cdot d}{\sqrt{S}}$. The height

which will produce this velocity is $\frac{N \cdot g}{2 \cdot G \cdot S} \left(\frac{w \cdot b}{w + 2 \cdot b} \right)$. Now this is the slope at the entry of the canal which produces the velocity that is afterwards maintained against the obstructions by the slope of the canal. It is therefore

$= H - b$. Hence we deduce $b = \frac{w \left(\frac{N \cdot g}{2 \cdot G \cdot S} + 1 \right) - 2 \cdot H}{4}$

$+ \sqrt{8 \cdot H \cdot w + \left(w \left(\frac{N \cdot g}{2 \cdot G \cdot S} + 1 \right) - 2 \cdot H \right)^2}$. If there be

no contraction at the entry, $g = G$ and $\frac{9}{2} \cdot G = \frac{1}{2}$.

Having thus obtained the depth b of the stream, we obtain the quantity of water by combining this with the width w and the velocity V .

But as this was but an approximation, it is necessary to examine whether the velocity V be possible. This is very easy. It must be produced by the fall $H - b$. We shall have no occasion for any correction of our first assumption, if b has not been extravagantly erroneous, because a small mistake in b produces almost the same variation in d . The test of accuracy, however, is; that b , together with the height which will produce the velocity V , must make up the whole height H . Assuming b too small leaves $H - b$ too great, and will give a small velocity V , which requires a small value of $H - b$. The error of $H - b$ therefore is always greater than the error we have committed in our first assumption. Therefore when this error of $H - b$ is but a trifle, such as one fourth of an inch, we may rest satisfied with our answer.

Perhaps the easiest process may be the following: Suppose the whole stream in train to have the depth H . The velocity V obtained for this depth and slope by the Table requires a certain productive height u . Make $\sqrt{H + u}$:

$H = H : b$, and b will be exceedingly near the truth. The reason is obvious.

Ques. 2. Given the discharge (or quantity to be furnished in a second) Q , the height H of the basin above the bottom of the canal, and the slope, to find the dimensions of the canal?

Let x and y be the depth and mean width. It is plain that the equation $\frac{Q}{x \cdot y} = \sqrt{2 \cdot G} \cdot \sqrt{H - x}$ will give a value of y in terms of x . Compare this with the value of y obtained from the equation $\frac{Q}{x \cdot y} = \frac{\sqrt{N} \cdot g}{\sqrt{S}} \cdot \sqrt{\frac{x \cdot y}{y + 2 \cdot x}}$. This

will give an equation containing only x and known quantities. But it will be very complicated, and we must have recourse to an approximation. This will be best understood in the form of an example.

Suppose the depth at the entry to be 18 inches, and the slope $\frac{1}{25}$. Let 1200 cubic feet of water per minute be the quantity of water to be drawn off, for working machinery or any other purpose; and let the canal be supposed of the best form, recommended in § 9. of the article RIVER, where the base of the sloping side is $\frac{3}{4}$ ds of the height.

The slightest consideration will show us that if $\frac{V}{7.4}$ be taken for the height producing the velocity, it cannot exceed 3 inches, nor be less than 1. Suppose it = 2, and therefore the depth of the stream in the canal to be 16 inches; find the mean width of the canal by the equation

$w = b \left(\sqrt{d} - c, 1 \right) \left(\frac{307}{\sqrt{S}} - c, 3 \right)$, in which Q is 20 cubic feet (the 60th part of 1200), \sqrt{S} is = 28,153, = $\sqrt{1000 - L \sqrt{1000 + 1,6}}$, and $b = 16$. This gives $w = 5,52$ feet. The section $n = 7,36$ feet, and $V = 32,6$ inches. This requires a fall of 1,52 inches instead of 2 inches. Take this from 18, and there remains 16,4, which we shall find not to differ $\frac{1}{2}$ h of an inch from the exact depth which the water will acquire and maintain. We may therefore be satisfied with assuming 5,46 feet as the mean width, and 3,53 feet for the width at the bottom.

This approximation proceeds on this consideration, that when the width diminishes by a small quantity, and in the same proportion that the depth increases, the hydraulic mean depth remains the same, and therefore the velocity also remains, and the quantity discharged changes in the exact proportion of the section. Any minute error which may result from this supposition, may be corrected by increasing the fall producing the velocity in the proportion of the hydraulic mean depth to the mean depth corresponding to the new dimensions found for the canal. It will now become 1,53, and V will be 32,7, and the depth will be 16,47. The quantity discharged being divided by V , will give the section = 7,355 feet, from which, and the new depth, we obtain 5,344 for the width.

This and the foregoing are the most common questions proposed to an engineer. We asserted with some confidence that few of the profession are able to answer them with tolerable precision. We cannot offend the professional gentlemen by this, when we inform them that the Academy of Sciences at Paris were occupied during several months with an examination of a plan proposed by M. Parcieux, for bringing the waters of the Yvette into Paris; and after the most mature consideration, gave in a report of the quantity of

water

Water-works.

water which M. De Parcieux's aqueduct would yield, and that their report has been found erroneous in the proportion of at least 2 to 5: For the waters have been brought in, and exceed the report in this proportion. Indeed long after the giving in the report, M. Perronet, the most celebrated engineer in France, assumed that the dimensions proposed were much greater than were necessary, and said, that an aqueduct of $5\frac{1}{2}$ feet wide, and $3\frac{1}{2}$ deep, with a slope of 15 inches in a thousand fathoms, would have a velocity of 12 or 13 inches *per* second, which would bring in all the water furnished by the proposed sources. The great diminution of expence occasioned by the alteration encouraged the community to undertake the work. It was accordingly begun, and a part executed. The water was found to run with a velocity of near 19 inches when it was $3\frac{1}{2}$ feet deep. M. Perronet founded his computation on his own experience alone, acknowledging that he had no theory to instruct him. The work was carried no farther, it being found that the city could be supplied at a much smaller expence by steam-engines erected by Boulton and Watt. But the facts which occurred in the partial execution of the aqueduct are very valuable. If M. Perronet's aqueduct be examined by our general formula, s will be found $= \frac{1875}{18}$, and $d = 18,72$, from which we deduce the velocity $= 18\frac{1}{2}$, agreeing with the observation with astonishing precision.

The experiments at Turin by Michælotti on canals were very numerous, but complicated with many circumstances which would render the discussion too long for this place. When cleared of these circumstances, which we have done with scrupulous care, they are also abundantly conformable to our theory of the uniform motion of running waters. But to return to our subject:

Should it be required to bring off at once from the basin a mill course, having a determined velocity for driving an under-shot wheel, the problem becomes easier, because the velocity and slope combined determine the hydraulic mean depth at once; and the depth of the stream will be had by means of the height which must be taken for the whole depth at the entry, in order to produce the required velocity.

In like manner, having given the quantity to be discharged, and the velocity and the depth at the entry, we can find the other dimensions of the channel; and the mean depth being found, we can determine the slope.

When the slope of a canal is very small, so that the depth of the uniform stream differs but a little from that at the entry, the quantity discharged is but small. But a great velocity, requiring a great fall at the entry, produces a great diminution of depth, and therefore it may not compensate for this diminution, and the quantity discharged may be smaller. Improbable as this may appear, it is not demonstrably false; and hence we may see the propriety of the following

Question 3. Given the depth H at the entry of a rectangular canal, and also its width w , required the slope, depth, and velocity, which will produce the greatest possible discharge?

Let x be the unknown depth of the stream. $H - x$ is the productive fall, and the velocity is $\sqrt{2G} \sqrt{H - x}$. This multiplied by $w x$ will give the quantity discharged. Therefore $w x \sqrt{2G} \sqrt{H - x}$ must be made a maximum. The common process for this will give the equation $2H = 3x$, or $x = \frac{2}{3}H$. The mean velocity will be $\sqrt{2G} \sqrt{\frac{1}{3}H}$; the section will be $\frac{2}{3}wH$, and the discharge $= \frac{2}{3}\sqrt{2G} w H \sqrt{\frac{1}{3}H}$, and $d = \frac{\frac{2}{3}wH}{\frac{2}{3} + \frac{1}{3}}$. With these

data the slope is easily had by the formula for uniform motion.

If the canal is of the trapezoidal form, the investigation is more troublesome, and requires the resolution of a cubic equation.

It may appear strange that increasing the slope of a canal beyond the quantity determined by this problem can diminish the quantity of water conveyed. But one of these two things must happen; either the motion will not acquire uniformity in such a canal for want of length, or the discharge must diminish. Supposing, however, that it could augment, we can judge how far this can go. Let us take the extreme case, by making the canal vertical. In this case it becomes a simple weir or wasteboard. Now the discharge of a wasteboard is $\frac{2}{3}\sqrt{2G} w (b^{\frac{3}{2}} - (\frac{1}{2}b)^{\frac{3}{2}})$. The maximum determined by the preceding problem is to that of the wasteboard of the same di-

mensions as $H \sqrt{\frac{1}{3}H} : H^{\frac{3}{2}} - (\frac{1}{2}H)^{\frac{3}{2}}$, or as $H \sqrt{\frac{1}{3}H} : H \sqrt{H} - \frac{1}{2}H \sqrt{\frac{1}{2}H}$, $= 5773 : 6465$, nearly $= 9 : 10$.

Having given the dimensions and slope of a canal, we can discover the relation between its expenditure and the time; or we can tell how much it will sink the surface of a pond in 24 hours, and the gradual progress of this effect; and this might be made the subject of a particular problem. But it is complicated and difficult. In cases where this is an interesting object, we may solve the question with sufficient accuracy, by calculating the expenditure at the beginning, supposing the basin kept full. Then, from the known area of the pond, we can tell in what time this expenditure will sink an inch; do the same on the supposition that the water is one-third lower, and that it is two-thirds lower (noticing the contraction of the surface of the pond occasioned by this abstraction of its waters). Thus we shall obtain three rates of diminution, from which we can easily deduce the desired relation between the expenditure and the time.

Aqueducts derived from a basin or river are commonly furnished with a sluice at the entry. This changes exceedingly the state of things. The slope of the canal may be precisely such as will maintain the mean velocity of the water which passes under the sluice; in which case the depth of the stream is equal to that of the sluice, and the velocity is produced at once by the head of water above it. But if the slope is less than this, the velocity of the issuing water is diminished, and the water must rise in the canal. This must check the efflux at the sluice, and the water will be as it were stagnant above what comes through below it. It is extremely difficult to determine at what precise slope the water will begin to check the efflux. The contraction at the lower edge of the board hinders the water from attaining at once the whole depth which it acquires afterwards, when its velocity diminishes by the obstructions. While the regorging which these obstructions occasion does not reach back to the sluice, the efflux is not affected by it.— Even when it does reach to the sluice, there will be a less depth immediately behind it than farther down the canal, where it is in train; because the swift moving water which is next the bottom drags with it the regorged water which lies on it: but the canal must be rapid to make this difference of depth sensible. In ordinary canals, with moderate slopes and velocities, the velocity at the sluice may be safely taken as if it were that which corresponds to the difference of depths above and below the sluice, where both are in train.

Let therefore H be the depth above the sluice, and b the depth in the canal. Let e be the elevation of the sluice above the sole, and let b be its breadth. The discharge will

will be $cb \sqrt{H-b} \sqrt{2G}$ for the sluice, and $wb \frac{\sqrt{Ng}}{\sqrt{s}}$

$\sqrt{\frac{wb}{w+2b}}$ for the canal. These must be the same.

This gives the equation $cb \sqrt{H-b} \sqrt{2G} = wb \frac{\sqrt{Ng}}{\sqrt{s}}$

$\sqrt{\frac{wb}{w+2b}}$ containing the solution of all the questions

which can be proposed. The only uncertainty is in the quantity G , which expresses the velocity competent to the passage of the water through the orifice, circumstanced as it is, namely, subjected to contraction. This may be regulated by a proper form given to the entry into this orifice. The contraction may be almost annihilated by making the maloury of a cycloidal form on both sides, and also at the lower edge of the sluice-board, so as to give the orifice a form resembling fig. 5. D, in the article RIVERS. If the sluice is thin in the face of a balon, the contraction will reduce $2G$ to 296 . If the sluice be as wide as the canal, $2G$ will be nearly 500 .

Question 4. Given the head of water in the basin H , the breadth b , and elevation e of the sluice, and the breadth w and slope s of the canal, to find the depth b of the stream, the velocity, and the discharge?

We must (as in *Question 2.*) make a first supposition for b , in order to find the proper value of d . Then the equation $cb \sqrt{H-b} \sqrt{2G} = wb \frac{\sqrt{Ng}}{\sqrt{s}}$ gives $b = \frac{C e^2 b^2 s}{w^2 N g d}$

$+ \sqrt{\frac{G e^2 b^2 s H}{w^2 N g d} + \left(\frac{G e^2 b^2 s}{w^2 N g d}\right)^2}$. If this value shall

differ considerably from the one which we assumed in order to begin the computation, make use of it for obtaining a new value of d , and repeat the operation. We shall rarely be obliged to perform a third operation.

The following is of frequent use:

Question 5. Given the dimensions and the slope, with the velocity and discharge of a river in its ordinary state, required the area or section of the sluice which will raise the waters to a certain height, still allowing the same quantity of water to pass through? Such an operation may render the river navigable for small craft or rafts above the sluice.

The problem is reduced to the determination of the size of orifice which will discharge this water with a velocity competent to the height to which the river is to be raised; only we must take into consideration the velocity of the water above the sluice, considering it as produced by a fall which makes a part of the height productive of the whole velocity at the sluice. Therefore H , in our investigation, must consist of the height to which we mean to raise the waters, and the height which will produce the velocity with which the waters approach the sluice: b , or the depth of the stream, is the ordinary depth of the river. Then (using

the former symbols) we have $cb \frac{wb \sqrt{Ng} d}{\sqrt{2Gs(H-b)}} =$

$$\frac{Q}{\sqrt{2G(H-b)}}$$

If the area of the sluice is known, and we would learn the height to which it will raise the river, we have $H-b$

$$= \frac{Q^2}{2G e^2 b^2}$$

for the expression of the rise of the water above its ordinary level. But from this we must take the height which would produce the velocity of the river; so that if the sluice were as wide as the river, and were raised

to the ordinary surface of the water, $\frac{Q^2}{2G e^2 b^2}$ which expresses the height that produces the velocity under the sluice, must be equal to the depth of the river, and $H-b$ will be $= 0$.

The performance of aqueduct drains is a very important thing, and merits our attention in this place. While the art of managing waters, and of conducting them so as to answer our demands, renders us very important service by embellishing our habitations, or promoting our commercial intercourse, the art of draining creates as it were new riches, fertilizing tracts of bog or marsh, which was not only useless, but hurtful by its unwholesome exhalations, and converting them into rich pastures and gay meadows. A wild country, occupied by marshes which are inaccessible to herds or flocks, and serve only for the haunts of water-fowls, or the retreat of a few poor fishermen, when once it is freed from the waters in which it is drowned, opens its lap to receive the most precious seeds, is soon clothed in the richest garb, gives life and abundance to numerous herds, and never fails to become the delight of the industrious cultivator who has enfranchised it, and is attached to it by the labour which it cost him. In return, it procures him abundance, and supplies him with the means of daily augmenting its fertility. No species of agriculture exhibits such long, continued, and progressive improvement. New families flock to the spot, and there multiply; and there nature seems the more eager to repay their labours, in proportion as she has been obliged, against her will, to keep her treasures locked up for a longer time, chilled by the waters. The countries newly inhabited by the human race, as is a great part of America, especially to the southward, are still covered to a great extent with marshes and lakes; and they would long remain in this condition, if population, daily making new advances, did not increase industry, by multiplying the cultivating hands, at the same time that it increases their wants. The Author of this beautiful world has at the beginning formed the great masses of mountain, has scooped out the dales and sloping hills, has traced out the courses, and even formed the beds of the rivers: but he has left to man the care of making his place of abode, and the field which must feed him, dry and comfortable. For this task is not beyond his powers, and the others are. Nay, by having this given to him in charge, he is richly repaid for his labour by the very state in which he finds those countries into which he penetrates for the first time. Being covered with lakes and forests, the juices of the soil are kept for him as it were in reserve. The air, the burning heat of the sun, and the continual washing of rains, would have combined to expend and dissipate their vegetative powers, had the fields been exposed in the same degree to their action as in the inhabited and cultivated countries, the most fertile moulds of which are long since lodged in the bottom of the ocean. All this would have been completely lost through the whole extent of South America, had it not been protected by the forests which man must cut down, by the rank herbage which he must burn, and by the marsh and bog which he must destroy by draining. Let not ungrateful man complain of this. It is his duty to take on himself the task of opening up treasures, preserved on purpose for him with so much judgment and care. If he has discernment and sensibility, he will even thank the Author of all good, who has thus husbanded them for his use. He will co-operate with his beneficent views, and will be careful not to proceed by wantonly snatching at present and partial good, and by picking out what is most easily got at, regardless of him

Water-works.

who is to come afterwards to uncover and extract the remaining riches of the ground. A wise administration of such a country will think it their duty to leave a just share of this inheritance to their descendants, who are entitled to expect it as the last legatees. National plans of cultivation should be formed on this principle, that the steps taken by the present cultivators for realizing part of the riches of the infant country shall not obstruct the works which will afterwards be necessary for also obtaining the remainder. This is carefully attended to in Holland and in China. No man is allowed to conduct the drains, by which he recovers a piece of marsh, in such a way as to render it much more difficult for a neighbour, or even for his own successor, to drain another piece, although it may at present be quite inaccessible. There remains in the middle of the most cultivated countries many marshes, which industry has not yet attempted to drain, and where the legislature has not been at pains to prevent many little abuses which have produced elevations in the beds of rivers, and rendered the complete draining of some spots impossible. Administration should attend to such things, because their consequences are great. The sciences and arts, by which alone these difficult and costly jobs can be performed, should be protected, encouraged, and cherished. It is only from science that we can obtain principles to direct these arts. The problem of draining canals is one of the most important, and yet has hardly ever occupied the attention of the hydraulic speculatist. We apprehend that Mr Buat's theory will throw great light on it; and regret that the very limited condition of our present Work will hardly afford room for a slight sketch of what may be done on the subject. We shall, however, attempt it by a general problem, which will involve most of the chief circumstances which occur in works of that kind.

Quæst. 6. Let the hollow ground A (fig. 2) be inundated by rains or springs, and have no outlet but the canal AB, by which it discharges its water into the neighbouring river BCDE, and that its surface is nearly on a level with that of the river at B. It can only drain when the river sinks in the droughts of summer; and even if it could then drain completely, the putrid marsh would only be an infecting neighbour. It may be proposed to drain it by one or more canals; and it is required to determine their lengths and other dimensions, so as to produce the best effects?

It is evident that there are many circumstances to determine the choice, and many conditions to be attended to.

If the canals AC, AD, AE, are respectively equal to the portions BC, BD, BE, of the river, and have the same slopes, they will have the same discharge: but they are not for this reason equivalent. The long canal AE may drain the marsh completely, while the short one AC will only do it in part; because the difference of level between A and C is but inconsiderable. Also the freshes of the river may totally obstruct the operation of AC, while the canal AE cannot be hurt by them, E being so much lower than C. Therefore the canal must be carried so far down the river, that no freshes there shall ever raise the waters in the canal so high as to reduce the slope in the upper part of it to such a level that the current shall not be sufficient to carry off the ordinary produce of water in the marsh.

Still the problem is indeterminate, admitting many solutions. This requisite discharge may be accomplished by a short but wide canal, or by a longer and narrower. Let us first see what solution can be made, so as to accomplish our purpose in the most economical manner, that is, by means of the smallest equation.—We shall give the solution in the form of an example.

Suppose that the daily produce of rains and springs raises the water $1\frac{1}{2}$ inch on an area of a square league, which gives about 120,000 cubic fathoms of water. Let the bottom of the basin be three feet below the surface of the freshes in the river at B in winter. Also, that the slope of the river is 2 inches in 100 fathoms, or $\frac{1}{50}$ depth, and that the canal is to be 6 feet deep.

The canal being supposed nearly parallel to the river, it must be at least 1800 fathoms long before it can be admitted into the river, otherwise the bottom of the bog will be lower than the mouth of the canal; and even then a hundred or two more fathoms added to this will give it so little slope, that an immense breadth will be necessary to make the discharge with so small a velocity. On the other hand, if the slope of the canal be made nearly equal to that of the river, an extravagant length will be necessary before its admission into the river, and many obstacles may then intervene. And even then it must have a breadth of 13 feet, as may easily be calculated by the general hydraulic theorem. By receding from each of these extremes, we shall diminish the expence of excavation. Therefore,

Let x and y be the breadth and length, and b the depth (6 feet), of the canal. Let q be the depth of the bog below the surface of the river, opposite to the basin, D the discharge in a second, and $\frac{1}{a}$ the slope of the river. We must make $b \times y$ a minimum, or $x \dot{y} + y \dot{x} = 0$.

The general formula gives the velocity $V = \frac{\sqrt{ng}(\sqrt{d-0,1})}{\sqrt{s-1}\sqrt{s+1,6}} = 0,3(\sqrt{d-0,1})$. This would give x and y ; but the logarithmic term renders it very complicated. We may make use of the simple form $V = \frac{\sqrt{Ngd}}{\sqrt{S}}$,

making \sqrt{Ng} nearly $2y$. This will be sufficiently exact for all cases which do not deviate far from this, because the velocities are very nearly in the subduplicate ratio of the slopes.

To introduce these data into the equation, recollect that $\dot{V} = \frac{D}{bx}$; $d = \frac{bx}{x+2b}$. As to S , recollect that the ^{at} canal being supposed of nearly equal length with the river, $\frac{y}{a}$ will express the whole difference of height, and $\frac{y}{a} - q$ is the difference of height for the canal. This quantity being

divided by y , gives the value of $\frac{1}{S} = \frac{y}{a} - q$. Therefore

the equation for the canal becomes $\sqrt{Ng} \sqrt{\frac{bx}{x+2b}} = \frac{Ngq b^3 x^3}{a}$. Hence we deduce $y = \frac{Ng b^3 x^3}{a} - D^2(x+2b)$

and $\dot{y} = \frac{3Ngqb^3x^2\dot{x}}{a} - D^2(x+2b)$
 $\frac{Ngqb^3x^3\dot{x}\left(\frac{3Ngqb^3x^2}{a} - D^2\right)}{\left(\frac{Ng b^3 x^3}{a} - D^2(x+2b)\right)^2}$. If we substitute these

values in the equation $y \dot{x} + x \dot{y} = 0$, and reduce it, we obtain finally,

$$\frac{Ng b^3 x^3}{a D^2} - 3x = 8b.$$

If we resolve this equation by making $Ng = (296)^2$, or 87616 inches; $b = 72$, $\frac{1}{a} = \frac{1}{1155}$, and $D = 518400$, we obtain $x = 392$ inches, or 32 feet 8 inches, and $\frac{D}{b^2x}$ or $V = 18,36$ inches. Now, putting these values in the exact formula for the velocity, we obtain the slope of the canal, which is $\frac{1}{1155}$, nearly 0,62 inches in 100 fathoms.

Let l be the length of the canal in fathoms. As the river has 2 inches fall in 100 fathoms, the whole fall is $\frac{2l}{100}$, and that of the canal is $\frac{0,62l}{100}$. The difference of these two must be 3 feet, which is the difference between the river and the entry of the canal. We have therefore $(\frac{2-0,62}{100})l = 36$ inches. Hence $l = 2604$ fathoms; and this multiplied by the section of the canal gives 14177 cubic fathoms of earth to be removed.

This may surely be done, in most cases, for eight shillings each cubic fathom, which does not amount to 6000l. a very moderate sum for completely draining of nine square miles of country.

In order to judge of the importance of this problem, we have added two other canals, one longer and the other shorter, having their widths and slopes so adjusted as to ensure the same performance.

Width. Velocity. Slope. Length. Excavation.

Feet.	Inches.			
42	14,28	$\frac{1}{1155}$	2221	15547
32 $\frac{2}{3}$	18,36	$\frac{1}{1155}$	2604	14177
21	28,57	$\frac{1}{1155}$	7381	25833

We have considered this important problem in its most simple state. If the basin is far from the river, so that the drains are not nearly parallel to it, and therefore have less slope attainable in their course, it is more difficult. Perhaps the best method is to try two very extreme cases and a middle one, and then a fourth, nearer to that extreme which differs least from the middle one in the quantity of excavation. This will point out on which side the minimum of excavation lies, and also the law by which it diminishes and afterwards increases. Then draw a line, on which set off from one end the lengths of the canals. At each length erect an ordinate representing the excavation; and draw a regular curve through the extremities of the ordinates. From that point of the curve which is nearest to the base line, draw another ordinate to the base. This will point out the best length of the canal with sufficient accuracy. The length will determine the slope, and this will give the width, by means of the general theorem. *N. B.* These draining canals must always come off from the basin with elevated entries. This will prevent the loss of much fall at the entry.

Two canals may sometimes be necessary. In this case expence may frequently be saved, by making one canal flow into the other. This, however, must be at such a distance from the basin, that the swell produced in the other by this addition may not reach back to the immediate neighbourhood of the basin, otherwise it would impede the performance of both. For this purpose, recourse must be had to the problem iii. in n^o 104. of the article RIVER. We must here observe, that in this respect canals differ exceedingly from rivers: rivers enlarge their beds, so as always to convey every increase of waters; but a canal may be gorged through its whole length, and will then greatly diminish its discharge. In order that the lower extremity of a canal may convey the waters of an equal canal admitted in-

to it, their junction must be so far from the basin, that the swell occasioned by raising its waters nearly $\frac{1}{2}$ more (viz. in the subduplicate ratio of 1 to 2) may not reach back to the basin.

This observation points out another method of economy. Instead of one wide canal, we may make a narrower one of the whole length, and another narrow one reaching part of the way, and communicating with the long canal at a proper distance from the basin. But the lower extremity will now be too shallow to convey the waters of both. Therefore raise its banks by using the earth taken from its bed, which must at any rate be disposed of. Thus the waters will be conveyed, and the expence, even of the lower part of the long canal, will scarcely be increased.

These observations must suffice for an account of the management of open canals; and we proceed to the consideration of the conduct of water in pipes.

This is much more simple and regular, and the general theorem requires very trifling modifications for adapting it to the cases or questions that occur in the practice of the civil engineer. Pipes are always made round, and therefore d is always $\frac{1}{2}$ th of the diameter. The velocity of water in a pipe which is in train, is $= V = \frac{307(\sqrt{d-0,1})}{\sqrt{s-L}\sqrt{s+1,6}}$

$= 0,3(\sqrt{d-0,1})$ or $= (\sqrt{d-0,1}) \left(\frac{307}{\sqrt{s-L}\sqrt{s+1,6}} - 0,3 \right)$.

The chief questions are the following:

Quest. 1. Given the height H of the reservoir above the place of delivery, and the diameter and length of the pipe, to find the quantity of water discharged in a second?

Let L be the length, and b the fall which would produce the velocity with which the water enters the pipe, and actually flows in it, after overcoming all obstructions. This may be expressed in terms of the velocity by $\frac{V^2}{2G}$, G denoting the acceleration of gravity, corresponding to the manner of entry. When no methods are adopted for facilitating the entry of the water, by a bell-shaped funnel or otherwise, $2G$ may be assumed as $= 500$ inches, or 42 feet, according as we measure the velocity in inches or feet.

The slope is $\frac{1}{s} = \frac{H - \frac{V^2}{2G}}{L}$, which must be put into the general formula. This would make it very complicated. We may simplify it by the consideration that the velocity is very small in comparison of that arising from the height H : consequently b is very small. Also, in the same pipe, the resistances are nearly in the duplicate ratio of the velocities when these are small, and when they differ little among themselves. Therefore make $b = \frac{L}{b}$, taking b by guess, a very little less than H . Then compute the mean velocity v corresponding to these data, or take it from the table. If $b + \frac{v^2}{2G} = H$, we have found the mean velocity $V = v$. If not, make the following proportion: $b : \frac{v^2}{2G} = H - \frac{V^2}{2G} : \frac{V^2}{2G}$, which is the same with this $b + \frac{v^2}{2G} : v^2 = H : V^2$, and V^2 is $= \frac{v^2 H}{b + \frac{v^2}{2G}} = \frac{v^2 H}{\frac{2Gb + v^2}{2G}} = \frac{v^2 \cdot 2GH}{v^2 + 2Gb}$.

to it, their junction must be so far from the basin, that the swell occasioned by raising its waters nearly $\frac{1}{2}$ more (viz. in the subduplicate ratio of 1 to 2) may not reach back to the basin.

Water-works.

This observation points out another method of economy. Instead of one wide canal, we may make a narrower one of the whole length, and another narrow one reaching part of the way, and communicating with the long canal at a proper distance from the basin. But the lower extremity will now be too shallow to convey the waters of both. Therefore raise its banks by using the earth taken from its bed, which must at any rate be disposed of. Thus the waters will be conveyed, and the expence, even of the lower part of the long canal, will scarcely be increased.

These observations must suffice for an account of the management of open canals; and we proceed to the consideration of the conduct of water in pipes.

This is much more simple and regular, and the general theorem requires very trifling modifications for adapting it to the cases or questions that occur in the practice of the civil engineer. Pipes are always made round, and therefore d is always $\frac{1}{2}$ th of the diameter. The velocity of water in a pipe which is in train, is $= V = \frac{307(\sqrt{d-0,1})}{\sqrt{s-L}\sqrt{s+1,6}}$

$= 0,3(\sqrt{d-0,1})$ or $= (\sqrt{d-0,1}) \left(\frac{307}{\sqrt{s-L}\sqrt{s+1,6}} - 0,3 \right)$.

The chief questions are the following:

Quest. 1. Given the height H of the reservoir above the place of delivery, and the diameter and length of the pipe, to find the quantity of water discharged in a second?

Let L be the length, and b the fall which would produce the velocity with which the water enters the pipe, and actually flows in it, after overcoming all obstructions. This may be expressed in terms of the velocity by $\frac{V^2}{2G}$, G denoting the acceleration of gravity, corresponding to the manner of entry. When no methods are adopted for facilitating the entry of the water, by a bell-shaped funnel or otherwise, $2G$ may be assumed as $= 500$ inches, or 42 feet, according as we measure the velocity in inches or feet.

The slope is $\frac{1}{s} = \frac{H - \frac{V^2}{2G}}{L}$, which must be put into the general formula. This would make it very complicated. We may simplify it by the consideration that the velocity is very small in comparison of that arising from the height H : consequently b is very small. Also, in the same pipe, the resistances are nearly in the duplicate ratio of the velocities when these are small, and when they differ little among themselves. Therefore make $b = \frac{L}{b}$, taking b by guess, a very little less than H . Then compute the mean velocity v corresponding to these data, or take it from the table. If $b + \frac{v^2}{2G} = H$, we have found the mean velocity $V = v$. If not, make the following proportion: $b : \frac{v^2}{2G} = H - \frac{V^2}{2G} : \frac{V^2}{2G}$, which is the same with this $b + \frac{v^2}{2G} : v^2 = H : V^2$, and V^2 is $= \frac{v^2 H}{b + \frac{v^2}{2G}} = \frac{v^2 H}{\frac{2Gb + v^2}{2G}} = \frac{v^2 \cdot 2GH}{v^2 + 2Gb}$.

Therefore make $b = \frac{L}{b}$, taking b by guess, a very little less than H . Then compute the mean velocity v corresponding to these data, or take it from the table. If $b + \frac{v^2}{2G} = H$, we have found the mean velocity $V = v$. If not, make the following proportion: $b : \frac{v^2}{2G} = H - \frac{V^2}{2G} : \frac{V^2}{2G}$, which is the same with this $b + \frac{v^2}{2G} : v^2 = H : V^2$, and V^2 is $= \frac{v^2 H}{b + \frac{v^2}{2G}} = \frac{v^2 H}{\frac{2Gb + v^2}{2G}} = \frac{v^2 \cdot 2GH}{v^2 + 2Gb}$.

Therefore make $b = \frac{L}{b}$, taking b by guess, a very little less than H . Then compute the mean velocity v corresponding to these data, or take it from the table. If $b + \frac{v^2}{2G} = H$, we have found the mean velocity $V = v$. If not, make the following proportion: $b : \frac{v^2}{2G} = H - \frac{V^2}{2G} : \frac{V^2}{2G}$, which is the same with this $b + \frac{v^2}{2G} : v^2 = H : V^2$, and V^2 is $= \frac{v^2 H}{b + \frac{v^2}{2G}} = \frac{v^2 H}{\frac{2Gb + v^2}{2G}} = \frac{v^2 \cdot 2GH}{v^2 + 2Gb}$.

Therefore make $b = \frac{L}{b}$, taking b by guess, a very little less than H . Then compute the mean velocity v corresponding to these data, or take it from the table. If $b + \frac{v^2}{2G} = H$, we have found the mean velocity $V = v$. If not, make the following proportion: $b : \frac{v^2}{2G} = H - \frac{V^2}{2G} : \frac{V^2}{2G}$, which is the same with this $b + \frac{v^2}{2G} : v^2 = H : V^2$, and V^2 is $= \frac{v^2 H}{b + \frac{v^2}{2G}} = \frac{v^2 H}{\frac{2Gb + v^2}{2G}} = \frac{v^2 \cdot 2GH}{v^2 + 2Gb}$.

Therefore make $b = \frac{L}{b}$, taking b by guess, a very little less than H . Then compute the mean velocity v corresponding to these data, or take it from the table. If $b + \frac{v^2}{2G} = H$, we have found the mean velocity $V = v$. If not, make the following proportion: $b : \frac{v^2}{2G} = H - \frac{V^2}{2G} : \frac{V^2}{2G}$, which is the same with this $b + \frac{v^2}{2G} : v^2 = H : V^2$, and V^2 is $= \frac{v^2 H}{b + \frac{v^2}{2G}} = \frac{v^2 H}{\frac{2Gb + v^2}{2G}} = \frac{v^2 \cdot 2GH}{v^2 + 2Gb}$.

Water-works.

If the pipe has any bendings, they must be calculated for in the manner mentioned in the article RIVER, n^o 101; and the head of water necessary for overcoming this additional resistance being called $\frac{V^2}{m}$, the last proportion must be changed for

$$h + v^2 \left(\frac{1}{2G} + \frac{1}{m} \right) : v^2 = H : V^2.$$

Quest. 2d. Given the height of the reservoir, the length of the pipe, and the quantity of water which is to be drawn off in a second, to find the diameter of the pipe which will draw it off?

Let d be considered as $\frac{1}{4}$ th of the diameter, and let $1 : c$ represent the ratio of the diameter of a circle to its circumference. The section of the pipe is $4cd^2$. Let the quantity of water *per* second be Q ; then $\frac{Q}{4cd^2}$ is the mean velocity. Divide the length of the pipe by the height of the reservoir above the place of delivery, diminished by a very small quantity, and call the quotient S . Consider this as the slope of the conduit; the general formula now becomes

$$\frac{Q}{4d^2} = \frac{307(\sqrt{d-0,1})}{\sqrt{s-L}\sqrt{s+1,06}} - 0,3(\sqrt{d-0,1}),$$

or $\frac{Q}{4cd^2} = \frac{307(\sqrt{d-0,1})}{\sqrt{S}} - 0,3(\sqrt{d-0,1})$. We may neglect the last term in every case of civil practice, and also the small quantity $0,1$: This gives the very simple formula

$$\frac{Q}{4cd^2} = \frac{307\sqrt{d}}{\sqrt{S}}$$

from which we readily deduce

$$d = \frac{Q\sqrt{S}}{4c \times 307}^{\frac{2}{3}} = \frac{Q\sqrt{S}}{3858}^{\frac{2}{3}}$$

This process gives the diameter somewhat too small. But we easily rectify this error by computing the quantity delivered by the pipe, which will differ a little from the quantity proposed. Then observing, by this equation, that two pipes having the same length and the same slope give quantities of water, of which the squares are nearly as the 5th powers of the diameter, we form a new diameter in this proportion, which will be almost perfectly exact.

It may be observed that the height assumed for determining the slope in these two questions will seldom differ more than an inch or two from the whole height of the reservoir above the place of delivery; for in conduits of a few hundred feet long the velocity seldom exceeds four feet *per* second, which requires only a head of 3 inches.

As no inconvenience worth minding results from making the pipes a tenth of an inch or so wider than is barely sufficient, and as this generally is more than the error arising from even a very erroneous assumption of b , the answer first obtained may be augmented by one or two tenths of an inch, and then we may be confident that our conduit will draw off the intended quantity of water.

We presume that every person who assumes the name of engineer knows how to reduce the quantity of water measured in gallons, piuts, or other denominations, to cubic inches, and can calculate the gallons, &c. furnished by a pipe of known diameter, moving with a velocity that is measured in inches *per* second. We farther suppose that all care is taken in the construction of the conduit, to avoid obstructions occasioned by lumps of folder hanging in the inside of the pipes; and, particularly, that all the cocks and plugs by the way have waterways equal to the section of the pipe. Undertakers are most tempted to fail here,

by making the cocks too small, because large cocks are very costly. But the employer should be scrupulously attentive to this; because a simple contraction of this kind may be the throwing away of many hundred pounds in a wide pipe, which yields no more water than can pass through the small cock.

The chief obstructions arise from the deposition of sand or mud in the lower parts of pipes, or the collection of air in the upper parts of their bendings. The velocity being always very moderate, such depositions of heavy matters are unavoidable. The utmost care should therefore be taken to have the water freed from all such things at its entry by proper filtration; and there ought to be cleansing plugs at the lower parts of the bendings, or rather a very little way beyond them. When these are opened, the water issues with greater velocity, and carries the depositions with it.

It is much more difficult to get rid of the air which chokes the pipes by lodging in their upper parts. This is sometimes taken in along with the water at the reservoir, when the entry of the pipe is too near the surface. This should be carefully avoided, and it costs no trouble to do so. If the entry of the pipe is two feet under the surface, no air can ever get in. Floats should be placed above the entries, having lids hanging from them, which will shut the pipe before the water runs too low.

But air is also disengaged from spring-water by merely passing along the pipe. When pipes are supplied by an engine, air is very often drawn in by the pumps in a disengaged state. It is also disengaged from its state of chemical union, when the pumps have a suction-pipe of 10 or 12 feet, which is very common. In whatever way it is introduced, it collects in all the upper part of bendings, and chokes the passage, so that sometimes not a drop of water is delivered. Our cocks should be placed there, which should be opened frequently by persons who have this in charge. Detaguliers describes a contrivance to be placed on all such eminences, which does this of itself. It is a pipe with a cock, terminating in a small cistern. The key of the cock has a hollow ball of copper at the end of a lever. When there is no air in the main pipe, water comes out by this discharger, fills the cistern, raises the ball, and thus shuts the cock. But when the bend of the main contains air, it rises into the cistern, and occupies the upper part of it. Thus the floating ball falls down, the cock opens and lets out the air, and the cistern again filling with water, the ball rises, and the cock is again shut.

A very neat contrivance for this purpose was invented by the late Professor Russel of Edinburgh. The cylindrical pipe BCDE (fig. 3.), at the upper part of a bending of the main, is screwed on, the upper end of which is a flat plate perforated with a small hole F. This pipe contains a hollow copper cylinder G, to the upper part of which is fastened a piece of soft leather H. When there is air in the pipe, it comes out by the hole A, and occupies the discharger, and then escapes through the hole F. The water follows, and, rising in the discharger, lifts up the hollow cylinder G, causing the leather H to apply itself to the plate CD, and shut the hole. Thus the air is discharged without the smallest loss of water.

It is of the most material consequence that there be no contraction in any part of a conduit. This is evident; but it is also prudent to avoid all unnecessary enlargements. For when the conduit is full of water moving along it, the velocity in every section is inversely proportional to the area of the section: it is therefore diminished wherever the pipe is enlarged; but it must again be increased where the pipe contracts. This cannot be without expending force in the acceleration. This consumes part of the impelling power, whether

whether this be a head of water, or the force of an engine. See what is said on this subject in the article PUMPS, n^o 83, &c. Nothing is gained by any enlargement; and every contraction, by requiring an augmentation of velocity, employs a part of the impelling force precisely equal to the weight of a column of water whose base is the contracted passage, and whose height is the fall which would produce a velocity equal to this augmentation. This point seems to have been quite overlooked by engineers of the first eminence, and has in many instances greatly diminished the performance of their best works. It is no less detrimental in open canals; because at every contraction a small fall is required for restoring the velocity lost in the enlargement of the canal, by which the general slope and velocity are diminished. Another point which must be attended to in the conducting of water is, that the motion should not be subsidiary, but continuous. When water is to be driven along a main by the strokes of a reciprocating engine, it should be forced into an air-box, the spring of which may preserve it in motion along the whole subsequent main. If the water is brought to rest at every successive stroke of the piston, the whole mass must again be put in motion through the whole length of the main. This requires the same useless expenditure of power as to communicate this motion to as much dead matter; and this is over and above the force which may be necessary for raising the water to a certain height; which is the only circumstance that enters into the calculation of the power of the pump-engine.

An air-box removes this imperfection, because it keeps up the motion during the returning stroke of the piston. The compression of the air by the active stroke of the piston must be such as to continue the impulse in opposition to the contrary pressure of the water (if it is to be raised to some height), and in opposition to the friction or other resistances which arise from the motion that the water really acquires. Indeed a very considerable force is employed here also in changing the motion of the water, which is forced out of the spacious air-box into the narrow pipe; and when this change of motion is not judiciously managed, the expenditure of power may be as great as if all were brought to rest and again put into motion. It may even be greater, by causing the water to move in the opposite direction to its former motion. Of such consequence is it to have all these circumstances scientifically considered. It is in such particulars, unheeded by the ordinary herd of engineers or pump-makers, that the superiority of an intelligent practitioner is to be seen.

Another material point in the conduit of water in pipes is the distribution of it to the different persons who have occasion for it. This is rarely done from the rising main. It is usual to send the whole into a cistern, from which it is afterwards conducted to different places in separate pipes. Till the discovery of the general theorem by the chevalier Buat, this has been done with great inaccuracy. Engineers think that the different purchasers from water-works receive in proportion to their respective bargains when they give them pipes whose areas are proportional to these payments. But we now see, that when these pipes are of any considerable length, the waters of a larger pipe run with a greater velocity than those of a smaller pipe having the same slope. A pipe of two inches diameter will give much more water than four pipes of one inch diameter; it will give as much as five and a half such pipes, or more; because the squares of the discharges are very nearly as the fifth powers of the diameters. This point ought therefore to be carefully considered in the bargains made with the proprietors of water-works, and the payments made in this proportion. Perhaps the most unexceptionable method would be to make

a double distribution. Let the water be first let off in its proper proportions into a second series of small cisterns, and let each have a pipe which will convey the whole water that is discharged into it. The first distribution may be made entirely by pipes of one inch in diameter; this would leave nothing to the calculation of the distributor, for every man would pay in proportion to the number of such pipes which run into his own cistern.

In many cases, however, water is distributed by pipes derived from a main. And here another circumstance comes into action. When water is passing along a pipe, its pressure on the sides of the pipe is diminished by its velocity; and if a pipe is now derived from it, the quantity drawn off is also diminished in the subduplicate ratio of the pressures. If the pressure is reduced to $\frac{1}{2}$ th, $\frac{1}{4}$ th, $\frac{1}{8}$ th, &c. the discharge from the lateral pipe is reduced to $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$ th, &c.

It is therefore of great importance to determine, what this diminution of pressure is which arises from the motion along the main.

It is plain, that if the water suffered no resistance in the main, its velocity would be that with which it entered, and it would pass along without exerting any pressure. If the pipe were shut at the end, the pressure on the sides would be the full pressure of the head of water. If the head of water remain the same, and the end of the tube be contracted, but not stopped entirely, the velocity in the pipe is diminished. If we would have the velocity in the pipe with this contracted mouth augmented to what it was before the contraction was made, we must employ the pressure of a piston, or of a head of water. This is propagated through the fluid, and thus a pressure is immediately excited on the sides of the pipe. New obstructions of any kind, arising from friction or any other cause, produce a diminution of velocity in the pipe. But when the natural velocity is checked, the particles react on what obstructs their motion; and this action is uniformly propagated through a perfect fluid in every direction. The resistance therefore which we thus ascribe to friction, produces the same lateral pressure which a contraction of the orifice, which equally diminishes the velocity in the pipe, would do. Indeed this is demonstrable from any distinct notions that we can form of these obstructions. They proceed from the want of perfect smoothness, which obliges the particles next the sides to move in undulated lines. This excites transverse forces in the same manner as any constrained curvilinear motion. A particle in its undulated path tends to escape from it, and acts on the lateral particles in the same manner that it would do if moving singly in a capillary tube having the same undulations; it would press on the concave side of every such undulation. Thus a pressure is exerted among the particles, which is propagated to the sides of the pipe; or the diminution of velocity may arise from a viscosity or want of perfect fluidity. This obliges the particle immediately pressed to drag along with it another particle which is withheld by adhesion to the sides. This requires additional pressure from a piston, or an additional head of water; and this pressure also is propagated to the sides of the pipe.

Hence it should follow, that the pressure which water in motion exerts on the sides of its conduit is equal to that which is competent to the head of water which impels it into the pipe, diminished by the head of water competent to the actual velocity with which it moves along the pipe. Let H represent the head of water which impels it into the entry of the pipe, and b the head which would produce the actual velocity; then $H - b$ is the column which would produce the pressure exerted on its sides.

This is abundantly verified by very simple experiments.

Water-works.

Let an upright pipe be inserted into the side of the main pipe. When the water runs out by the mouth of the main, it will rise in this branch till the weight of the column balances the pressure that supports it; and if we then ascertain the velocity of the issuing water by means of the quantity discharged, and compute the head or height necessary for producing this velocity, and subtract this from the height of water above the entry of the main, we shall find the height in the branch precisely equal to their difference. Our readers may see this by examining the experiments related by Gravesande, and still better by consulting the experiments narrated by Bossut, § 558, which are detailed with great minuteness; the results corresponded accurately with this proposition. The experiments indeed were not heights of water supported by this pressure, but water expelled by it through the same orifice. Indeed the truth of the proposition appears in every way we can consider the motion of water. And as it is of the first importance in the practice of conducting water (for reasons which will presently appear), it merits a particular attention. When an inclined tube is in train, the accelerating power of the water (or its weight diminished in the proportion of the length of the oblique column to its vertical height, or its weight multiplied by the fraction $\frac{1}{s}$, which expresses the slope), is in

equilibrium with the obstructions; and therefore it exerts no pressure on the pipe but what arises from its weight alone. Any part of it would continue to slide down the inclined plane with a constant velocity, though detached from what follows it. It therefore derives no pressure from the head of water which impelled it into the pipe. The same must be said of a horizontal pipe infinitely smooth, or opposing no resistance. The water would move in this pipe with the full velocity due to the head of water which impels it into the entry. But when the pipe opposes an obstruction, the head of water is greater than that which would impel it into the pipe with the velocity that it actually has in it; and this additional pressure is propagated along the pipe, where it is balanced by the actual resistance, and therefore excites a *quaqua versum* pressure on the pipe. In short, whatever part of the head of water in the reservoir, or of the pressure which impels it along the tube, is not employed in producing velocity, is employed in acting against some obstruction, and excites (by the reaction of this obstruction) an equal pressure on the tube. The rule therefore is general, but is subject to some modifications which deserve our attention.

In the simply inclined pipe BC (fig. 4.), the pressure on any point S is equal to that of the head AB of water which impels the water into the pipe wanting; or *minus* that of the head of water which would communicate to it the velocity with which it actually moves. This we shall call x , and consider it as the weight of a column of water whose length also is x . In like manner H may be the column AB, which impels the water into the pipe, and would communicate a certain velocity; and b may represent the column which would communicate the actual velocity. We have therefore $x = H - b$.

In the pipe HIKL, the pressure at the point I is $AH - b - IO$, $= H - b - IO$; and the pressure at K is $H - b + PK$.

And in the pipe DEFG, the pressure on E is $AR - b - EM$, $= H - b - EM$; and the pressure at F is $H - b + FN$.

We must carefully distinguish this pressure on any square inch of the pipe from the obstruction or resistance which that inch actually exerts, and which is part of the cause of this pressure. The pressure is (by the laws of hydrostatics) the same with that exerted on the water by a square inch

of the piston or forcing head of water. This must balance the united obstructions of the whole pipe, in as far as they are not balanced by the relative weight of the water in an inclosed pipe. Whatever be the inclination of a pipe, and the velocity of the water in it, there is a certain part of this resistance which may not be balanced by the tendency which the water has to slide along it, provided the pipe be long enough; or if the pipe is too short, the tendency down the pipe may more than balance all the resistances that obtain below. In the first case, this overplus must be balanced by an additional head of water; and in the latter case the pipe is not in train, and the water will accelerate. There is something in the mechanism of these motions which makes a certain length of pipe necessary for bringing it into train; a certain portion of the surface which acts in concert in obstructing the motion. We do not completely understand this circumstance, but we can form a pretty distinct notion of its mode of acting. The film of water contiguous to the pipe is withheld by the obstruction, but glides along; the film immediately within this is withheld by the outer film, but glides through it: and thus all the concentric films glide within those around them, somewhat like the sliding tubes of a spy-glass, when we draw it out by taking hold of the end of the innermost. Thus the second film passes beyond the first or outermost, and becomes the outermost, and rubs along the tube. The third does the same in its turn; and thus the central filaments come at last to the outside, and all sustain their greatest possible obstruction. When this is accomplished, the pipe is in train. This requires a certain length, which we cannot determine by theory. We see however that pipes of greater diameter must require a greater length, and this in a proportion which is probably that of the number of filaments, or the square of the diameter. Buat found this supposition agree well enough with his experiments. A pipe of one inch in diameter sustained no change of velocity by gradually shortening it till he reduced it to six feet, and then it discharged a little more water. A pipe of two inches diameter gave a sensible augmentation of velocity when shortened to 25 feet. He therefore says, that the square of the diameter in inches, multiplied by 72, will express (in inches) the length necessary for putting any pipe in train.

The resistance exerted by a square inch of the pipe makes but a small part of the pressure which the whole resistances occasion to be exerted there before they can be overcome.

The resistance may be represented by $\frac{d}{s}$, when d is the hydraulic depth ($\frac{1}{4}$ th of the diameter), and s the length of a column whose vertical height is one inch, and it is the relative weight of a column of water whose base is a square inch, and height is d . For the resistance of any length s of pipe which is in train, is equal to the tendency of the water to slide down (being balanced by it); that is, is equal to the weight of this column multiplied by $\frac{1}{s}$. The magnitude of this column is had by multiplying its length by its section. The section is the product of the border b or circumference, multiplied by the mean depth d , or it is bd . This, multiplied by the length, is $bd s$; and this multiplied by the slope $\frac{1}{s}$ is bd , the relative weight of the column whose length is s . The relative weight of one inch is therefore $\frac{bd}{s}$; and this is in equilibrium with the resistance of a ring of the pipe one inch broad. This, when unfolded, is a parallelogram b inches in length. One inch of this therefore

fore is $\frac{d}{s}$, the relative weight of a column of water having d for its height and a square inch for its base. Suppose the pipe four inches in diameter, and the slope = 253, the resistance is one grain; for an inch of water weighs 253 grains.

This knowledge of the pressure of water in motion is of great importance. In the management of rivers and canals it instructs us concerning the damages which they produce in their beds by tearing up the soil; it informs us of the strength which we must give to the banks: but it is of more consequence in the management of close conduits. By this we must regulate the strength of our pipes; by this also we must ascertain the quantities of water which may be drawn off by lateral branches from any main conduit.

With respect to the first of these objects, where security is our sole concern, it is proper to consider the pressure in the most unfavourable circumstances, viz. when the end of the main is shut. This case is not unfrequent. Nay, when the water is in motion, its velocity in a conduit seldom exceeds a very few feet in a second. Eight feet *per* second requires only one foot of water to produce it. We should therefore estimate the strain on all conduits by the whole height of the reservoir.

In order to adjust the strength of a pipe to the strain, we may conceive it as consisting of two half cylinders of insuperable strength, joined along the two seams, where the strength is the same with the ordinary strength of the materials of which it is made. The inside pressure tends to burst the pipe by tearing open these seams, and each of them sustains half of the strain. The strain on an inch of these two seams is equal to the weight of a column of water whose height is the depth of the seam below the surface of the reservoir, and whose base is an inch broad and a diameter of the pipe in length. This follows from the common principles of hydrostatics.

Suppose the pipe to be of lead, one foot in diameter and 100 feet under the surface of the reservoir. Water weighs $62\frac{1}{2}$ pounds *per* foot. The base of our column is therefore $\frac{1}{4}$ th of a foot, and the tendency to burst the pipe is $100 \times 62\frac{1}{2} \times \frac{1}{4}$ th = $1562\frac{1}{2}$ pounds nearly. Therefore an inch of one seam is strained by $260\frac{1}{2}$ pounds. A rod of lead one inch square is pulled asunder by 860 pounds (see *STRENGTH of Materials*, n^o 40). Therefore, if the thickness of the seam is $\frac{2}{3}$ inches, or $\frac{1}{3}$ d of an inch, it will just withstand this strain. But we must make it much stronger than this, especially if the pipe leads from an engine which sends the water along it by starts. Belidor and Desaguiliers have given tables of the thickness and weights of pipes which experience has found sufficient for the different materials and depths. Desaguiliers says, that a leaden pipe of $\frac{3}{4}$ ths of an inch in thickness is strong enough for a height of 140 feet and diameter of 7 inches. From this we may calculate all others. Belidor says, that a leaden pipe 12 inches diameter and 60 feet deep should be half an inch thick: but these things will be more properly computed by means of the list given in n^o 40 of the article *STRENGTH of Materials*.

The application which we are most anxious to make of the knowledge of the pressure of moving waters is the derivation from a main conduit by lateral branches. This occurs very frequently in the distribution of waters among the inhabitants of towns; and it is so imperfectly understood by the greatest part of those who take the name of engineers, that individuals have no security that they shall get even one half of the water they bargain and pay for; yet this may be as accurately ascertained as any other problem in hydraulics by means of our general theorem. The case therefore merits our particular attention.

It appears to be determined already, when we have ascertained the pressures by which the water is impelled into these lateral pipes, especially after we have said that the experiments of Bossut on the actual discharges from a lateral pipe fully confirm the theoretical doctrine. But much remains to be considered. We have seen that there is a vast difference between the discharge made through a hole, or even through a short pipe, and the discharge from the far end of a pipe derived from a main conduit. And even when this has been ascertained by our new theory, the discharge thus modified will be found considerably different from the real state of things: For when water is flowing along a main with a known velocity, and therefore exerting a known pressure on the circle which we propose for the entry of a branch, if we insert a branch there water will go along it: but this will generally make a considerable change in the motion along the main, and therefore in the pressure which is to expel the water. It also makes a considerable change in the whole quantity which passes along the anterior part of the main, and a still greater change on what moves along that part of it which lies beyond the branch: it therefore affects the quantity necessary for the whole supply, the force that is required for propelling it, and the quantity delivered by other branches. This part therefore of the management of water in conduits is of considerable importance and intricacy. We can propose in this place nothing more than a solution of such leading questions as involve the chief circumstances, recommending to our readers the perusal of original works on this subject. M. Bossut's experiments are fully competent to the establishment of the fundamental principle. The hole through which the lateral discharges were made was but a few feet from the reservoir. The pipe was successively lengthened, by which the resistances were increased, and the velocity diminished. But this did not affect the lateral discharges, except by affecting the pressures; and the discharges from the end of the main were supposed to be the same as when the lateral pipe was not inserted. Although this was not strictly true, the difference was insensible, because the lateral pipe had but about the 18th part of the area of the main.

Suppose that the discharge from the reservoir remains the same after the derivation of this branch, then the motion of the water all the way to the insertion of the branch is the same as before; but, beyond this, the discharge is diminished by all that is discharged by the branch, with the head x equivalent to the pressure on the side. The discharge by the lower end of the main being diminished, the velocity and resistance in it are also diminished. Therefore the difference between x and the head employed to overcome the friction in this second case, would be a needless or inefficient part of the whole load at the entry, which is impossible; for every force produces an effect, or it is destroyed by some reaction. The effect of the forcing head of water is to produce the greatest discharge corresponding to the obstructions; and thus the discharge from the reservoir, or the supply to the main, must be augmented by the insertion of the branch, if the forcing head of water remains the same. A greater portion therefore of the forcing head was employed in producing a greater discharge at the entry of the main, and the remainder, less than x , produced the pressure on the sides. This head was the one competent to the obstructions resulting from the velocity beyond the insertion of the branch: and this velocity, diminished by the discharge already made, was less than that at the entry, and even than that of the main without a branch. This will appear more distinctly by putting the case into the form of an equation. Therefore let $H - x$ be the height due to the velocity at the entry, of which the effect obtains only

horizontally. The head x is the only one which acts on the sides of the tube, tending to produce the discharge by the branch, at the same time that it must overcome the obstructions beyond the branch. If the orifice did not exist and if the force producing the velocity on a short tube be represented by $2G$, and the section of the main by A , the supply at the entry of the main would be $A\sqrt{2G}\sqrt{H-x}$; and if the orifice had no influence on the value of x , the discharge by the orifice would be $D\sqrt{\frac{x}{H}}$,

D being its discharge by means of the head H , when the end of the main is shut; for the discharges are in the subduplicate ratio of the heads of water by which they are expelled; and therefore $\sqrt{H} : \sqrt{x} = D : D\sqrt{\frac{x}{H}}$.

But we have seen that x must diminish; and we know that the obstructions are nearly as the square roots of the velocities, when these do not differ much among themselves. Therefore calling y the pressure or head which balances the resistances of the main without a branch, while x is the head necessary for the main with a branch, we may institute this proportion $y : H - y = x : \frac{x(H-y)}{y}$; and this 4th term will express the head producing the velocity in the main beyond the branch (as $H - y$ would have done in a main without a branch). This velocity beyond the branch will be $\sqrt{2G}\sqrt{\frac{x(H-y)}{y}}$, and the discharge at the end will be $A\sqrt{2G}\sqrt{\frac{x(H-y)}{y}}$. If to this we add the discharge of the branch, the sum will be the whole discharge, and therefore the whole supply. Therefore we have the following equation, $A\sqrt{2G}\sqrt{H-y} = A\sqrt{2G}\sqrt{\frac{x(H-y)}{y}} + D\sqrt{\frac{x}{H}}$. From this we deduce the value of $x = \frac{2GHA^2}{\left(A\sqrt{2G}\sqrt{\frac{H-y}{y}} + \frac{D}{\sqrt{H}}\right)^2} + 2GA^2$. This value of x being substituted in the equation of the discharge d of the branch, which was $= D\sqrt{\frac{x}{H}}$, will give the discharges required, and they will differ so much the more from the discharges calculated according to the simple theory, as the velocity in the main is greater. By the simple theory, we mean the supposition that the lateral discharges are such as would be produced by the head $H - b$, where H is the height of the reservoir, and b the head due to the actual velocity in the main.

And thus it appears that the proportion of the discharge by a lateral pipe from a main that is shut at the far end, and the discharge from a main that is open, depends not only on the pressures, but also on the size of the lateral pipe, and its distance from the reservoir. When it is large, it greatly alters the train of the main, under the same head, by altering the discharge at its extremity, and the velocity in it beyond the branch; and if it be near the reservoir, it greatly alters the train, because the diminished velocity takes place through a greater extent, and there is a greater diminution of the resistances.

When the branch is taken off at a considerable distance from the reservoir, the problem becomes more complicated, and the head x is resolved into two parts; one of which bal-

ances the resistance in the first part of the main, and the other balances the resistances beyond the lateral pipe, with a velocity diminished by the discharge from the branch.— A branch at the end of the main produces very little change in the train of the pipe.

When the lateral discharge is great, the train may be so altered, that the remaining part of the main will not run full, and then the branch will not yield the same quantity. The velocity in a very long horizontal tube may be so small (by a small head of water and great obstructions in a very long tube) that it will just run full. An orifice made in its upper side will yield nothing; and yet a small tube inserted into it will carry a column almost as high as the reservoir. So that we cannot judge in all cases of the pressures by the discharges, and *vice versa*.

If there be an inclined tube, having a head greater than what is competent to the velocity, we may bring it into train by an opening on its upper side near the reservoir. This will yield some water, and the velocity will diminish in the tube till it is in train. If we should now enlarge the hole, it will yield no more water than before.

And thus we have pointed out the chief circumstances which affect these lateral discharges. The discharges are afterwards modified by the conduits in which they are conveyed to their places of destination. These being generally of small dimensions, for the sake of economy, the velocity is much diminished. But, at the same time, it approaches nearer to that which the same conduit would bring directly from the reservoir, because its small velocity will produce a less change in the train of the main conduit.

We should now treat of jets of water, which still make an ornament in the magnificent pleasure grounds of the wealthy. Some of these are indeed grand objects, such as the two at Peterhoff in Russia, which spout about 60 feet high a column of nine inches diameter, which falls again, and shakes the ground with its blow. Even a spout of an inch or two inches diameter, lancing to the height of 150 feet, is a gay object, and greatly enlivens a pleasure-ground; especially when the changes of a gentle breeze bend the jet to one side. But we have no room left for treating this subject, which is of some nicety; and must conclude this article with a very short account of the management of water as an active power for impelling machinery.

II. Of Machinery drawn by Water.

THIS is a very comprehensive article, including almost every possible species of mill. It is no less important, and it is therefore matter of regret, that we cannot enter into the detail which it deserves. The mere description of the immense variety of mills which are in general use, would fill volumes, and a scientific description of their principles and maxims of construction would almost form a complete body of mechanical science. But this is far beyond the limits of a Work like ours. Many of these machines have been already described under their proper names, or under the articles which give an account of their manufactures; and for others we must refer our readers to the original works, where they are described in minute detail. The great academical collection *Des Arts et Metiers*, published at Paris in many folio volumes, contains a description of the peculiar machinery of many mills; and the volumes of the *Encyclopédie Methodique*, which particularly relate to the mechanic arts, already contain many more. All that we can do in this place is, to consider the chief circumstances that are common to all water-mills, and from which all must derive their efficacy. These circumstances are to be found in the manner of employing water as an acting power, and most of them

them are comprehended in the construction of water-wheels. When we have explained the principles and the maxims of construction of a water-wheel, every reader conversant in mechanics knows, that the axis of this wheel may be employed to transmit the force impressed on it to any species of machinery. Therefore nothing subsequent to this can with propriety be considered as *water-works*.

Water-wheels are of two kinds, distinguished by the manner in which water is made an impelling power, viz. by its weight, or by its impulse. This requires a very different form and manner of adaptation; and this forms an ostensible distinction, sufficiently obvious to give a name to each class. When water is made to act by its weight, it is delivered from the spout as high on the wheel as possible, that it may continue long to press it down: but when it is made to strike the wheel, it is delivered as low as possible, that it may have previously acquired a great velocity. And thus the wheels are said to be **OVERSHOT** or **UNDERSHOT**.

Of Overshot Wheels.

This is nothing but a frame of open buckets, so disposed round the rim of a wheel as to receive the water delivered from a spout; so that one side of the wheel is loaded with water, while the other is empty. The consequence must be, that the loaded side must descend. By this motion the water runs out of the lower buckets, while the empty buckets of the rising side of the wheel come under the spout in their turn, and are filled with water.

If it were possible to construct the buckets in such a manner as to remain completely filled with water till they come to the very bottom of the wheel, the pressure with which the water urges the wheel round its axis would be the same as if the extremity of the horizontal radius were continually loaded with a quantity of water sufficient to fill a square pipe, whose section is equal to that of the bucket, and whose length is the diameter of the wheel. For let the buckets BD and EF (fig. 5.) be compared together, the arches DB and EF are equal. The mechanical energy of the water contained in the bucket EF, or the pressure with which its weight urges the wheel, is the same as it all this water were hung on that point T of the horizontal arm CF, where it is cut by the vertical or plumb-line BT. This is plain from the most elementary principles of mechanics. Therefore the effect of the bucket BD is to that of the bucket EF as CT to CF or CB. Draw the horizontal lines PB *bb*, QD *dd*. It is plain, that if BD is taken very small, so that it may be considered as a straight line, BD : BO = CB : BP, and EF : *bd* = CF : CT, and EF × CT = *bd* × CF. Therefore if the prism of water, whose vertical section is *bbdd*, were hung on at F, its force to urge the wheel round would be the same as that of the water lying in the bucket BD. The same may be said of every bucket; and the effective pressure of the whole ring of water A *f* HKFI, in its natural situation, is the same with the pillar of water *abbba* hung on at F. And the effect of any portion BF of this ring is the same with that of the corresponding portion *bFfb* of the vertical pillar. We do not take into account the small difference which arises from the depth B or F *f*, because we may suppose the circle described through the centres of gravity of the buckets. And in the farther prosecution of this subject, we shall take similar liberties, with the view of simplifying the subject, and saving time to the reader.

But such a state of the wheel is impossible. The bucket at the very top of the wheel may be completely filled with water; but when it comes into the oblique position BD, a part of the water must run over the outer edge *s*, and the bucket will only retain the quantity ZBD *s*; and if the

buckets are formed by partitions directed to the axis of the wheel, the whole water must be run out by the time that they descend to the level of the axis. To prevent this many contrivances have been adopted. The wheel has been surrounded with a hoop or sweep, consisting of a circular board, which comes almost into contact with the rim of the wheel, and terminates at H, where the water is allowed to run off. But unless the work is executed with uncommon accuracy, the wheel made exactly round, and the sweep exactly fitting it, a great quantity of water escapes between them; and there is a very sensible obstruction to the motion of such a wheel, from something like friction between the water and the sweep. Frost also effectually stops the motion of such a wheel. Sweeps have therefore been generally laid aside, although there are situations where they might be used with good effect.

Mill-wrights have turned their whole attention to the giving a form to the buckets which shall enable them to retain the water along a great portion of the circumference of the wheel. It would be endless to describe all these contrivances; and we shall therefore content ourselves with one or two of the most approved. The intelligent reader will readily see that many of the circumstances which concur in producing the ultimate effect (such as the facility with which the water is received into the buckets, the place which it is to occupy during the progress of the bucket from the top to the bottom of the wheel, the readiness with which they are evacuated, or the chance that the water has of being dragged beyond the bottom of the wheel by its adhesion, &c. &c.) are such as do not admit of precise calculation or reasoning about their merits; and that this or that form can seldom be evidently demonstrated to be the very best possible. But, at the same time, he will see the general reasons of preference, and his attention will be directed to circumstances which must be attended to, in order to have a good bucketted wheel.

Fig. 6. is the outline of a wheel having 40 buckets. The ring of board contained between the concentric circles QDS and PAR, making the ends of the buckets, is called the **SHROUDING**, in the language of the art, and QP is called the *depth of shrouding*. The inner circle PAR is called the **SOLS** of the wheel, and usually consists of boards nailed to strong wooden rings of compass timber of considerable scantling, firmly united with the **ARMS** or radii. The partitions, which determine the form of the buckets, consist of three different planes or boards AB, BC, CD, which are variously named by different artists. We have heard them named the **START** or **SHOULDER**, the **ARM**, and the **WREST** (probably for wrist, on account of a resemblance of the whole line to the human arm); B is also called the **ELBOW**. Fig. 7. represents a small portion of the same bucketing on a larger scale, that the proportions of the parts may be more distinctly seen. AG, the sole of one bucket, is made about $\frac{1}{7}$ th more than the depth GH of the shrouding. The start AB is $\frac{1}{4}$ of AL. The plane BC is so inclined to AB that it would pass through H; but it is made to terminate in C, in such a manner that FC is $\frac{1}{2}$ ths of GH or AI. Then CD is so placed that HD is about $\frac{1}{7}$ th of IH.

By this construction, it follows that the area FABC is very nearly equal to DABC; so that the water which will fill the space FABC will all be contained in the bucket when it shall come into such a position that AD is a horizontal line; and the line AB will then make an angle of nearly 35° with the vertical, or the bucket will be 35° from the perpendicular. If the bucket descend so much lower that one half of the water runs out, the line AB will make an angle of 25°, or 24° nearly, with the vertical. There-

Water-works.

Water-works.

fore the wheel, filled to the degree now mentioned, will begin to lose water at about $\frac{1}{3}$ th of the diameter from the bottom, and *half of the water will be discharged* from the lowest bucket, about $\frac{1}{2}$ th of the diameter farther down. These situations of the discharging bucket are marked at T and V in fig. 6. Had a greater proportion of the buckets been filled with water when they were under the spout, the discharge would have begun at a greater height from the bottom, and we should lose a greater portion of the whole fall of water. The loss by the present construction is less than $\frac{1}{5}$ th (supposing the water to be delivered into the wheel at the very top), and may be estimated at about $\frac{1}{7}$ th; for the loss is the versed sine of the angle which the radius of the bucket makes with the vertical. The versed sine of 35° is nearly $\frac{1}{7}$ th of the radius (being 0,18085), or $\frac{1}{7}$ th of the diameter. It is evident, that if only $\frac{1}{4}$ of this water were supplied to each bucket as it passes the spout, it would have been retained for 10° more of a revolution, and the loss of fall would have been only about $\frac{1}{15}$ th.

These observations serve to show; in general, that an advantage is gained by having the buckets so capacious that the quantity of water which each can receive as it passes the spout may not nearly fill it. This may be accomplished by making them of a sufficient length, that is, by making the wheel sufficiently broad between the two shroudings. Economy is the only objection to this practice, and it is generally very ill placed. When the work to be performed by the wheel is great, the addition of power gained by a greater breadth will soon compensate for the additional expence.

The third plane CD is not very frequent; and mill-wrights generally content themselves with continuing the board all the way from the elbow B to the outer edge of the wheel at H; and AB is generally no more than $\frac{1}{4}$ d of the depth AI. But CD is a very evident improvement, causing the wheel to retain a very sensible addition to the water. Some indeed make this addition more considerable, by bringing BC more outward, so as to meet the rim of the wheel at H, for instance, and making HD coincide with the rim. But this makes the entry of the water somewhat more difficult during the very short time that the opening of the bucket passes the spout. To facilitate this as much as possible, the water should get a direction from the spout, such as will send it into the buckets in the most perfect manner. This may be obtained by delivering the water through an aperture that is divided by thin plates of board or metal, placed in the proper position, as we have represented in fig. 6. The form of bucket last mentioned, having the wrest concentric with the rim, is unfavourable to the ready admission of the water; whereas an oblique wrest conducts the water which has missed one bucket into the next below.

The mechanical consideration of this subject also shows us, that a deep shrouding, in order to make a capacious bucket, is not a good method: it does not make the buckets retain their water any longer; and it diminishes the effective fall of water: for the water received at the top of the wheel immediately falls to the bottom of the bucket, and thus shortens the fictitious pillar of water, which we showed to be the measure of the effective or useful pressure on the wheel: and this concurs with our former reasons for recommending as great a breadth of the wheel, and length of buckets, as economical considerations will permit.

A bucket wheel has been executed lately by Mr Robert Burns, at the cotton-mills of Houston, Burns, and Co. at Cartside in Renfrewshire, of a construction entirely new, but founded on a good principle, which is susceptible of

great extension. It is represented in fig. 8. The bucket consists of a flart AB, an arm BC, and a wrest CD, concentric with the rim. But the bucket is also divided by a partition LM, concentric with the sole and rim, and so placed as to make the inner and outer portions of nearly equal capacity. It is evident, without any farther reasoning about it, that this partition will enable the bucket to retain its water much longer. When they are filled $\frac{1}{4}$ d, they retain the whole water at 18° from the bottom; and they retain $\frac{1}{2}$ at 11° . They do not admit the water quite so freely as buckets of the common construction; but by means of the contrivance mentioned a little ago for the spout (also the invention of Mr Burns, and furnished with a rack-work, which raised or depressed it as the supply of water varied, so as at all times to employ the whole fall of the water), it is found, that a slow-moving wheel allows one-half of the water to get into the inner buckets, especially if the partition do not altogether reach the radius drawn through the lip D of the outer bucket.

This is a very great improvement of the bucket-wheel; and when the wheel is made of a liberal breadth, so that the water may be very shallow in the buckets, it seems to carry the performance as far as it can go. Mr Burns made the first trial on a wheel of 24 feet diameter; and its performance is manifestly superior to that of the wheel which it replaced, and which was a very good one. It has also another valuable property: When the supply of water is very scanty, a proper adjustment of the apparatus in the spout will direct almost the whole of the water into the outer buckets; which, by placing it at a greater distance from the axis, makes a very sensible addition to its mechanical energy.

We said that this principle is susceptible of considerable extension; and it is evident that two partitions will increase the effect, and that it will increase with the number of partitions: so that when the practice now begun, of making water-wheels of iron, shall become general, and therefore very thin partitions are used, their number may be greatly increased without any inconvenience: and it is obvious, that this series of partitions must greatly contribute to the stiffness and general firmness of the whole wheel.

There frequently occurs a difficulty in the making of bucket-wheels, when the half-taught mill-wright attempts to retain the water a long time in the buckets. The water gets into them with a difficulty which he cannot account for, and spills all about, even when the buckets are not moving away from the spout. This arises from the air, which must find its way out to admit the water, but is obstructed by the entering water, and occasions a great sputtering at the entry. This may be entirely prevented by making the spout considerably narrower than the wheel. This will leave room at the two ends of the buckets for the escape of the air. This obstruction is vastly greater than one would imagine; for the water drags along with it a great quantity of air, as is evident in the *Water-blast* described by many authors.

There is another and very serious obstruction to the motion of an overshot or bucketed wheel. When it moves in back-water, it is not only resisted by the water, when it moves more slowly than the wheel, which is very frequently the case, but it lifts a great deal in the rising buckets. In some particular states of back-water, the descending bucket fills itself completely with water; and, in other cases, it contains a very considerable quantity, and air of common density; while in some rarer cases it contains less water, with air in a condensed state. In the first case, the rising bucket must come up filled with water, which it cannot drop till its mouth get out of the water. In the second

W.

cond case, part of the water goes out before this; but the air rarefies, and therefore there is still some water dragged or lifted up by the wheel, by suction as it is usually called. In the last case there is no such back load on the rising side of the wheel, but (which is as detrimental to its performance) the descending side is employed in condensing air; and although this air aids the ascent of the rising side, it does not aid it so much as it impedes the descending side, being (by the form of the bucket) nearer to the vertical line drawn thro' the axis.

All this may be completely prevented by a few holes made in the sturt of each bucket. Air being at least 800 times rarer than water, will escape through a hole almost 30 times faster with the same pressure. Very moderate holes will therefore suffice for this purpose: and the small quantity of water which these holes discharge during the descent of the buckets, produces a loss which is altogether insignificant. The water which runs out of one runs into another, so that there is only the loss of one bucket. We have seen a wheel of only 14 feet diameter working in nearly three feet of back-water. It laboured prodigiously, and brought up a great load of water, which fell from it in abrupt dashes, which rendered the motion very hobbling. When three holes of an inch diameter were made in each bucket (12 feet long), the wheel laboured no more, there was no more plunging of water from its rising side, and its power on the machinery was increased more than $\frac{1}{4}$ th.

These practical observations may contain information that is new even to several experienced mill-wrights. To persons less informed they cannot fail of being useful. We now proceed to consider the action of water thus lying in the buckets of a wheel; and to ascertain its energy as it may be modified by different circumstances of fall, velocity, &c.

With respect to variations in the fall, there can be little room for discussion. Since the active pressure is measured by the pillar of water reaching from the horizontal plane where it is delivered on the wheel, to the horizontal plane where it is spilled by the wheel, it is evident that it must be proportional to this pillar, and therefore we must deliver it as high and retain it as long as possible.

This maxim obliges us, in the first place, to use a wheel whose diameter is equal to the whole fall. We shall not gain any thing by employing a larger wheel; for although we should gain by using only that part of the circumference where the weight will act more perpendicularly to the radius, we shall lose more by the necessity of discharging the water at a greater height from the bottom: For we must suppose the buckets of both the wheels equally well-constructed; in which case, the heights above the bottom, where they will discharge the water, will increase in the proportion of the diameter of the wheel. Now, that we shall lose more by this than we gain by a more direct application of the weight, is plain, without any further reasoning, by taking the extreme case, and supposing our wheel enlarged to such a size, that the useless part below is equal to our whole fall. In this case the water will be spilled from the buckets as soon as it is delivered into them. All intermediate cases, therefore, partake of the imperfection of this.

When our fall is exceedingly great, a wheel of an equal diameter becomes enormously big and expensive, and is of itself an unmanageable load. We have seen wheels of 58 feet diameter, however, which worked extremely well; but they are of very difficult construction, and extremely apt to warp and go out of shape by their weight. In cases like this, where we are unwilling to lose any part of the force of a small stream, the best form of a bucket-wheel is

an inverted chain-pump. Instead of employing a chain-pump of the best construction, ABCDEA (fig. 9.) to raise water through the upright pipe CB, by means of a force applied to the upper wheel A, let the water be delivered from a spout F, into the upper part of the pipe BC, and it will press down the plugs in the lower and narrower bored part of it with the full weight of the column, and escape at the dead level of C. This weight will urge round the wheel A without any defalcation: and this is the most powerful manner that any fall of water whatever can be applied, and exceeds the most perfect overshot wheel. But though it excels all chains of buckets in economy and in effect, it has all the other imperfections of this kind of machinery. Though the chain of plugs be of great strength, it has so much motion in its joints that it needs frequent repairs; and when it breaks, it is generally in the neighbourhood of A, on the loaded side, and all comes down with a great crash. There is also a loss of power by the immersion of so many plugs and chains in the water; for there can be no doubt but that if the plugs were big enough and light enough, they would buoy and even draw up the plugs in the narrow part at C. They must therefore diminish, in all other cases, the force with which this plug is pressed down.

The velocity of an overshot wheel is a matter of very great nicety; and authors, both speculative and practical, have entertained different, nay opposite, opinions on the subject. Mr Beledor, whom the engineers of Europe have long been accustomed to regard as sacred authority, maintains, that there is a certain velocity related to that obtainable by the whole fall, which will procure to an overshot wheel the greatest performance. Desaguliers, Smeaton, Lambert, Des Parcieux, and others, maintain, that there is no such relation, and that the performance of an overshot-wheel will be the greater, as it moves more slowly by an increase of its load of work. Beledor maintains, that the active power of water lying in a bucket-wheel of any diameter is equal to that of the impulse of the same water on the floats of an undershot wheel, when the water issues from a sluice in the bottom of the dam. The other writers whom we have named assert, that the energy of an undershot-wheel is but one-half of that of an overshot, actuated by the same quantity of water falling from the same height.

To a manufacturing country like ours, which derives astonishing superiority, by which it more than compensates for the impediments of heavy taxes and luxurious living chiefly from its machinery, in which it leaves all Europe far behind, the decision of this question, in such a manner as shall leave no doubt or misconception in the mind even of an unlettered artist, must be considered as a material service; and we think that this is easily attainable.

When any machine moves uniformly, the accelerating force or pressure actually exerted on the impelled point of the machine is in equilibrio with all the resistances which are exerted at the working point with those arising from friction, and those that are excited in different parts of the machine by their mutual actions. This is an incontestable truth; and though little attended to by the mechanicians, is the foundation of all practical knowledge of machines. Therefore, when an overshot-wheel moves uniformly, with *any velocity whatever*, the water is acting with its whole weight: for gravity would accelerate its descent, if not completely balanced by some reaction; and in this balance gravity and the reacting part of the machine exert equal and opposite pressures, and thus produce the uniform motion of the machine. We are thus particular on this point, because we observe mechanicians of the first

Water-works.

same employing a mode of reasoning on the question now before us which is specious, and appears to prove the conclusion which they draw; but is nevertheless contrary to true mechanical principles. They assert, that the slower a heavy body is descending (suppose in a scale suspended from an axis in peritrochæa), the more does it press on the scale, and the more does it urge the machine round: and therefore the slower an overshot wheel turns, the greater is the force with which the water urges it round, and the more work will be done. It is very true that the machine is more forcibly impelled, and that more work is done: but this is not because a pound of water presses more strongly, but because there is more water pressing on the wheel; for the spout supplies at the same rate, and each bucket receives more water as it passes by it.

Let us therefore examine this question by the unquestionable principles of mechanics.

Let the overshot-wheel *AfH* (fig. 5.) receive the water from a spout at the very top of the wheel; and, in order that the wheel may not be retarded by dragging into motion the water simply laid into the uppermost bucket at *A*, let it be received at *B*, with the velocity (directed in a tangent to the wheel) acquired by the head of water *AP*. This velocity, therefore, must be equal to that of the rim of the wheel. Let this be *v*, or let the wheel and the water move over *v* inches in a second. Let the buckets be of such dimensions, that all the water which each receives as it passes the spout is retained till it comes to the position *R*, where it is discharged at once. It is plain that, in place of the separate quantities of water lying in each bucket, we may substitute a continued ring of water, equal to their sum, and uniformly distributed in the space *BERfβ*. This constitutes a ring of uniform thickness. Let the area of its cross section *EB* or *Ff* be called *a*. We have already demonstrated, that the mechanical energy with which this water on the circumference of the wheel urges it round, is the same with what would be exerted by the pillar *brrb* pressing on *Ff*, or acting by the lever *CF*. The weight of this pillar may be expressed by $a \times br$, or $a \times PS$; and if we call the radius *CF* of the wheel *R*, the momentum or mechanical energy of this weight will be represented by $a \times PS \times R$.

Now, let us suppose that this wheel is employed to raise a weight *W*, which is suspended by a rope wound round the axis of the wheel. Let *r* be the radius of this axle. Then $W \times r$ is the momentum of the work. Let the weight rise with the velocity *u* when the rim of the wheel turns with the velocity *v*, that is, let it rise *u* inches in a second.

Since a perfect equilibrium obtains between the power and the work when the motion is uniform, we must have $W \times r = a \times PS \times R$. But it is evident that $R : r = v : u$. Therefore $W \times u = a \times v \times PS$.

Now the performance of the machine is undoubtedly measured by the weight and the height to which it is raised in a second, or by $W \times u$. Therefore the machine is in its best possible state when $a \times v \times PS$ is a maximum. But it is plain that $a \times v$ is an invariable quantity; for it is the cubic inches of water which the spout supplies in a second. If the wheel moves fast, little water lies in each bucket, and *a* is small. When *v* is small, *a* is great, for the opposite reason; but $a \times v$ remains the same. Therefore we must make *PS* a maximum, that is, we must deliver the water as high up as possible. But this diminishes *AP*, and this diminishes the velocity of the wheel: and as this has no limit, the proposition is demonstrated; and an overshot wheel does the more work as it moves slowest.

Convincing as this discussion must be to any mechanician,

we are anxious to impress the same maxim on the minds of practical men, unaccustomed to mathematical reasoning of any kind. We therefore beg indulgence for adding a popular view of the question, which requires no such investigation.

We may reason in this way: Suppose a wheel having 30 buckets, and that six cubic feet of water are delivered in a second on the top of the wheel, and discharged without any loss by the way at a certain height from the bottom of the wheel. Let this be the case, whatever is the rate of the wheel's motion; the buckets being of a sufficient capacity to hold all the water which falls into them. Let this wheel be employed to raise a weight of any kind, suppose water in a chain of 30 buckets, to the same height, and with the same velocity. Suppose, farther, that when the load on the rising side of the machine is one-half of that on the wheel, the wheel makes four times in a minute, or one turn in 15 seconds. During this time 90 cubic feet of water have flowed into the 30 buckets, and each has received three cubic feet. Then each of the rising buckets contains $1\frac{1}{2}$ feet; and 45 cubic feet are delivered into the upper cistern during one turn of the wheel, and 180 cubic feet in one minute.

Now, suppose the machine so loaded, by making the rising buckets more capacious, that it makes only two turns in a minute, or one turn in 30 seconds. Then each descending bucket must contain six cubic feet of water. If each bucket of the rising side contained three cubic feet, the motion of the machine would be the same as before. This is a point which no mechanician will controvert. When two pounds are suspended to one end of a string which passes over a pulley, and one pound to the other end, the descent of the two pound will be the same with that of a four pounds weight, which is employed in the same manner to draw up two pounds. Our machine would therefore continue to make four turns in the minute, and would deliver 90 cubic feet during each turn, and 360 in a minute. But, by supposition, it is making but two turns in a minute: this must proceed from a greater load than three cubic feet of water in each rising bucket. The machine must therefore be raising more than 90 feet of water during one turn of the wheel, and more than 180 in the minute.

Thus it appears, that if the machine is turning twice as slow as before, there is more than twice the former quantity in the rising buckets, and more will be raised in a minute by the same expenditure of power. In like manner, if the machine go three times as slow, there must be more than three times the former quantity of water in the rising buckets, and more work will be done.

But we may go farther, and assert, that the more we retard the machine, by loading it with more work of a similar kind, the greater will be its performance. This does not immediately appear from the present discussion: But let us call the first quantity of water in the rising bucket *A*; the water raised by four turns in a minute will be $4 \times 30 \times A = 120A$. The quantity in this bucket, when the machine goes twice as slow, has been shown to be greater than $2A$ (call it $2A + x$); the water raised by two turns in a minute will be $2 \times 30 \times 2A + x = 120A + 60x$. Now, let the machine go four times as slow, making but one turn in a minute, the rising bucket must now contain more than twice $2A + x$, or more than $4A + 2x$; call it $4A + 2x + y$. The work done by one turn in a minute will now be $30 \times 4A + 2x + y = 120A + 60x + 30y$.

By such an induction of the work, done with any rates of motion we choose, it is evident that the performance of the

the machine increases with every diminution of its velocity that is produced by the mere addition of a similar load of work, or that it does the more work the slower it goes.

We have supposed the machine to be in its state of permanent uniform motion. If we consider it only in the beginning of its motion, the result is still more in favour of slow motion: For, at the first action of the moving power, the inertia of the machine itself consumes part of it, and it acquires its permanent speed by degrees; during which, the resistances arising from the work, friction, &c. increase, till they exactly balance the pressure of the water; and after this the machine accelerates no more. Now the greater the power and the resistance arising from the work are, in proportion to the inertia of the machine, the sooner will all arrive at its state of permanent velocity.

There is another circumstance which impairs the performance of an overshot-wheel moving with a great velocity, viz. the effects of the centrifugal force on the water in the buckets. Our mill-wrights know well enough, that too great velocity will throw the water out of the buckets; but few, if any, know exactly the diminution of power produced by this cause. The following very simple construction will determine this: Let AOB (fig. 10.) be an overshot wheel, of which AB is the upright diameter, and C is the centre. Make CF the length of a pendulum, which will make two vibrations during one turn of the wheel. Draw FE to the elbow of any of the buckets. The water in this bucket, instead of having its surface horizontal, as NO, will have it in the direction nO perpendicular to FE very nearly.

For the time of falling along half of FC is to that of two vibrations of this pendulum, or to the time of a revolution of the wheel as the radius of a circle is to its circumference: and it is well known, that the time of moving along half of AC, by the uniform action of the centrifugal force, is to that of a revolution as the radius of a circle to its circumference. Therefore the time of describing $\frac{1}{2}$ of AC by the centrifugal force, is equal to the time of describing $\frac{1}{2}$ of FC by gravity. These spaces, being similarly described in equal times, are proportional to the accelerating forces. Therefore $\frac{1}{2} FC : \frac{1}{2} AC$, or $FC : AC = \text{gravity} : \text{centrifugal force}$. Complete the parallelogram FCEK. A particle at E is urged by its weight in the direction KE, with a force which may be expressed by FC or KE; and it is urged by the centrifugal force in the direction CE, with a force = AC or CE. By their combined action it is urged in the direction FE. Therefore, as the surface of standing water is always at right angles to the action of gravity, that is, to the plum-line, so the surface of the water in the revolving bucket is perpendicular to the action of the combined force FE.

Let NEO be the position of the bucket, which just holds all the water which it received as it passed the spout when not affected by the centrifugal force; and let NDO be its position when it would be empty. Let the vertical lines through D and E cut the circle described round C with the radius CF in the points H and I. Draw HC, IC, cutting the circle AOB in L and M. Make the arch d^d equal to AL, and the arch e^e equal to AM: Then C^d and C^e will be the positions of the bucket on the revolving wheel, corresponding to CDO and CEO on the wheel at rest. Water will begin to run out at e , and it will be all gone at d .—The demonstration is evident.

The force which now urges the wheel is still the weight really in the buckets: For though the water is urged in the direction and with the force FE, one of its constituents, CE, has no tendency to impel the wheel; and KE is the only impelling force.

It is but of late years that mills have been constructed or attended to with that accuracy and scientific skill which are necessary for deducing confidential conclusions from any experiments that can be made with them; and it is therefore no matter of wonder that the opinions of mill-wrights have been so different on this subject. There is a natural wish to see a machine moving briskly; it has the appearance of activity: but a very slow motion always looks as if the machine were overloaded. For this reason mill-wrights have always yielded slowly, and with some reluctance, to the repeated advices of the mathematicians: but they have yielded; and we see them adopting maxims of construction more agreeable to sound theory; making their wheels of great breadth, and loading them with a great deal of work. Mr Euler says, that the performance of the best mill cannot exceed that of the worst above $\frac{1}{4}$ th: but we have seen a stream of water completely expended in driving a small flax mill, which now drives a cotton mill of 4000 spindles, with all its carding, roving, and drawing machinery, besides the lathes and other engines of the smith and carpenters workshops, exerting a force not less than ten times what sufficed for the flax-mill.

The above discussion only demonstrates in general the advantage of slow motion; but does not point out in any degree the relation between the rate of motion and the work performed, nor even the principles on which it depends. Yet this is a subject fit for a mathematical investigation; and we would prosecute it in this place, if it were necessary for the improvement of practical mechanics. But we have seen that there is not, in the nature of things, a maximum of performance attached to any particular rate of motion which should therefore be preferred. For this reason we omit this discussion of mere speculative curiosity. It is very intricate: For we must not now express the pressure on the wheel by a constant pillar of water incumbent on the extremity of the horizontal arm, as we did before when we supposed the buckets completely filled; nor by a smaller constant pillar, corresponding to a smaller but equal quantity lying in every bucket. Each different velocity puts a different quantity of water into the bucket as it passes the spout; and this occasions a difference in the place where the discharge is begun and completed. This circumstance is some obstacle to the advantages of very slow motions, because it brings on the discharge sooner. All this may indeed be expressed by a simple equation of easy management; but the whole process of the mechanical discussion is both intricate and tedious, and the results are so much diversified by the forms of the buckets, that they do not afford any rule of sufficient generality to reward our trouble. The curious reader may see a very full investigation of this subject in two dissertations by Elvius in the Swedish Transactions, and in the *Hydrodynamique* of Professor Karltner of Gottingen; who has abridged these Dissertations of Elvius, and considerably improved the whole investigation, and has added some comparisons of his deductions with the actual performance of some great works. These comparisons, however, are not very satisfactory. There is also a valuable paper on this subject by Mr Lambert, in the Memoirs of the Academy of Berlin for the year 1775. From these dissertations, and from the *Hydrodynamique* of the Abbé Bossut, the reader will get all that theory can teach of the relation between the pressures of the power and work on the machine and the rates of its motion. The practical reader may rest with confidence on the simple demonstration we have given, that the performance is improved by diminishing the velocity.

All we have to do, therefore, is to load the machine, and thus to diminish its speed, unless other physical circumstances throw obstacles in the way: but there are such ob-

Water-
wheels.

Water-works.

stacks. In all machines there are little inequalities of action that are unavoidable. In the action of a wheel and pinion, though made with the utmost judgment and care, there are such inequalities. These increase by the changes of form occasioned by the wearing of the machine—much greater irregularities arise from the subsultory motions of cranks, stampers, and other parts which move unequally or reciprocally. A machine may be so loaded as just to be in equilibrio with its work, in the favourable position of its parts. When this changes into one less favourable, the machine may stop; if not, it at least staggers, hobbles, or works unequally. The rubbing parts bear long on each other, with enormous pressures, and cut deep, and increase friction. Such slow motions must therefore be avoided. A little more velocity enables the machine to get over those increased resistances by its inertia, or the great quantity of motion inherent in it. Great machines possess this advantage in a superior degree, and will therefore work steadily with a smaller velocity. These circumstances are hardly susceptible of mathematical discussion, and our best reliance is on well directed experience.

For this purpose, the reader will do well to peruse with care the excellent paper by Mr Smeaton in the Philosophical Transactions for 1759. This dissertation contains a numerous list of experiments, most judiciously contrived by him, and executed with the accuracy and attention, to the most important circumstances, which is to be observed in all that gentleman's performances.

It is true, these experiments were made with small models; and we must not, without great caution, transfer the results of such experiments to large works. But we may safely transfer the *laws* of variation which result from a variation of circumstances, although we must not adopt the absolute quantities of the variations themselves. Mr Smeaton was fully aware of the limitations to which conclusions drawn from experiments on models are subject, and has made the applications with his usual sagacity.

His general inference is, that, in smaller works, the rim of the overshot-wheel should not have a greater velocity than three feet in a second; but that larger mills may be allowed a greater velocity than this. When every thing is executed in the best manner, he says that the work performed will amount to fully two-thirds of the power expended; that is, that three cubic feet of water descending from any height will raise two to the same height. See some farther account of this dissertation under the word MECHANICS, sect. 5.

It is not very easy to compare these deductions with observations on large works; because there are few cases where we have good measures of the resistances opposed by the work performed by the machine. Mills employed for pumping water afford the best opportunities. But the inertia of their working gear diminishes their useful performance very sensibly; because their great beams, pump-rods, &c. have a reciprocating motion, which must be destroyed, and produced anew in every stroke. We have examined some machines of this kind which are esteemed good ones; and we find few of them whose performance exceeds one half of the power expended.

By comparing other mills with these, we get the best information of their resistances. The comparison with mills worked by Watt, and Boulton's steam-engines is perhaps a better measure of the resistances opposed by different kinds of work, because their power is very distinctly known. We have been informed by one of the most eminent engineers, that a ton and half of water *per minute* falling one foot will grind and dress one bushel of wheat *per hour*. This is equivalent to 9 tons falling 10 feet.

If an overshot-wheel opposed no resistance, and only one bucket were filled, the wheel would acquire the velocity due to a fall through the whole height. But when it is in this state of accelerated motion, if another bucket of water is delivered into it, its motion must be checked at the first, by the necessity of dragging forward this water. If the buckets fill in succession as they pass the spout, the velocity acquired by an unresisting wheel is but half of that which one bucket would give. In all cases, therefore, the velocity is diminished by the inertia of the entering water when it is simply laid into the upper buckets. The performance will therefore be improved by delivering the water on the wheel with that velocity with which the wheel is really moving. And as we cannot give the direction of a tangent to the wheel, the velocity with which it is delivered on the wheel must be so much greater than the intended velocity of the rim, that it shall be precisely equal to it when it is estimated in the direction of the tangent. Three or four inches of fall are sufficient for this purpose; and it should never be neglected, for it has a very sensible influence on the performance. But it is highly improper to give it more than this, with the view of impelling the wheel by its stroke. For even although it were proper to employ part of the fall in this way (which we shall presently see to be very improper), we cannot procure this impulse; because the water falls, among other water, or it strikes the boards of the wheel with such obliquity that it cannot produce any sensible effect.

It is a much debated question among mill-wrights, Whether the diameter of the wheel should be such as that the water will be delivered at the top of the wheel? or larger, so that the water is received at some distance from the top, where it will act more perpendicularly to the arm? We apprehend that the observations formerly made will decide in favour of the first practice. The space below, where the water is discharged from the wheel, being proportional to the diameter of the wheel, there is an undoubted loss of fall attending a large wheel; and this is not compensated by delivering the water at a greater distance from the perpendicular. We should therefore recommend the use of the whole descending side, and make the diameter of the wheel no greater than the fall, till it is so much reduced that the centrifugal force begins to produce a sensible effect. Since the rim can hardly have a smaller velocity than three feet *per second*, it is evident that a small wheel must revolve more rapidly. This made it proper to insert the determination that we have given, of the loss of power produced by the centrifugal force. But even with this in view, we should employ much smaller wheels than are generally done on small falls. Indeed the loss of water at the bottom may be diminished, by nicely fitting the arch which surrounds the wheel, so as not to allow the water to escape by the sides or bottom. While this improvement remains in good order, and the wheel entire, it produces a very sensible effect; but the passage widens continually by the wearing of the wheel. A bit of stick or stone falling in about the wheel-tears off part of the shrouding or bucket, and frosty weather frequently binds all fast. It therefore seldom answers expectations. We have nothing to add on this case to what we have already extracted from Mr Smeaton's Dissertation on the Subject of Breast or half Overshot Wheels.

There is another form of wheel by which water is made to act on a machine by its weight, which merits consideration. This is known in this country by the name of *Barber's mill*, and has been described by Desaguilliers, vol. ii. p. 460. It consists of an upright pipe or trunk AB (fig. 11.), communicating with two horizontal branches BC, Bc, which have a hole Cc near their ends, opening in opposite direc-

directions, at right angles to their lengths. Suppose water to be poured in at the top from the spout F, it will run out by the holes C and c with the velocity corresponding to the depth of these holes under the surface. The consequence of this must be, that the arms will be pressed backwards; for there is no solid surface at the hole C, or which the lateral pressure of the water can be exerted, while it acts with its full force on the opposite side of the arm. This unbalanced pressure is equal to the weight of a column having the orifice for its base, and twice the depth under the surface of the water in the trunk for its height. This measure of the height may seem odd, because if the orifice were shut, the pressure on it is the weight of a column reaching from the surface. But when it is open, the water issues with nearly the velocity acquired by falling from the surface, and the quantity of motion produced is that of a column of twice this length, moving with this velocity. This is actually produced by the pressure of the fluid, and must therefore be accompanied by an equal reaction.

Now suppose this apparatus set on the pivot E, and to have a spindle AD above the trunk, furnished with a cylindrical bobbin D, having a rope wound round it, and passing over a pulley G. A weight W may be suspended there, which may balance this backward pressure. If the weight be too small for this purpose, the retrograde motion of the arms will wind up the cord, and raise the weight; and thus we obtain an acting machine, employing the pressure of the water, and applicable to any purpose. A runner millstone may be put on the top of the spindle; and we should then produce a flour mill of the utmost simplicity, having neither wheel nor pinion, and subject to hardly any wear. It is somewhat surprising, that although this was invented at the beginning of this century, and appears to have such advantage in point of simplicity, it has not come into use. So little has Dr Desaguliers's account been attended to (although it is mentioned by him as an excellent machine, and as highly instructive to the hydraulist), that the same invention was again brought forward by a German professor (Segner) as his own, and has been honoured by a series of elaborate disquisitions concerning its theory and performance by Euler and by John Bernoulli. Euler's Dissertations are to be found in the Memoirs of the Academy of Berlin, 1751, &c. and in the *Nov. Comment. Petropol.* tom. vi. Bernoulli's are at the end of his *Hydraulics*. Both these authors agree in saying, that this machine excels all other methods of employing the force of water. Simple as it appears, its true theory, and the best form of construction, are most abstruse and delicate subjects; and it is not easy to give such an account of its principles as will be understood by an ordinary reader.

We see, in general, that the machine must press backwards; and little investigation suffices for understanding the intensity of this pressure, when the machine is at rest. But when it is allowed to run backwards, withdrawing itself from the pressure, the intensity of it is diminished; and if no other circumstances intervened, it might not be difficult to say what particular pressure corresponded to any rate of motion. Accordingly, Desaguliers, presuming on the simplicity of the machine, affirms the pressure to be the weight of a column, which would produce a velocity of efflux equal to the difference of the velocity of the fluid and of the machine; and hence he deduces, that its performance will be the greatest possible, when its retrograde velocity is one-third of the velocity acquired by falling from the surface, in which case, it will raise $\frac{8}{7}$ ths of the water expended to the same height, which is double of the performance of a mill acted on by the impulse of water.

But this is a very imperfect account of the operation.

When the machine (constructed exactly as we have described) moves round, the water which issues descends in the vertical trunk, and then, moving along the horizontal arms, partakes of this circular motion. This excites a centrifugal force, which is exerted against the ends of the arms by the intervention of the fluid. The whole fluid is subjected to this pressure (increasing for every section across the arm in the proportion of its distance from the axis), and every particle is pressed with the accumulated centrifugal forces of all the sections that are nearer to the axis. Every section therefore sustains an actual pressure proportional to the square of its distance from the axis. This increases the velocity of efflux, and this increases the velocity of revolution; and this mutual co-operation would seem to terminate in an infinite velocity of both motions. But, on the other hand, this circular motion must be given anew to every particle of water as it enters the horizontal arm. This can be done only by the motion already in the arm, and at its expence. Thus there must be a velocity which cannot be overpassed even by an unloaded machine. But it is also plain, that by making the horizontal arm very capacious, the motion of the water from the axis to the jet may be made very slow, and much of this diminution of circular motion prevented. Accordingly, Euler has recommended a form by which this is done in the most eminent degree. His machine consists of a hollow conoidal ring, of which fig. 12. is a section. The part AHba is a sort of funnel basin, which receives the water from the spout F; not in the direction pointing towards the axis, but in the direction, and with the precise velocity, of its motion. This prevents any retardation by dragging forward the water. The water then passes down between the outer conoid ACca and the inner conoid HGgb along spiral channels formed by partitions folded to both conoids. The curves of these channels are determined by a theory which aims at the annihilation of all unnecessary and improper motions of the water, but which is too abstruse to find a place here. The water thus conducted arrives at the bottom CG, *cg*. On the outer circumference of this bottom are arranged a number of spouts (one for each channel), which are all directed one way in tangents to the circumference.

Adopting the common theory of the reaction of fluids, this should be a very powerful machine, and should raise $\frac{8}{7}$ ths of the water expended. But if we admit the reaction to be equal to the force of the issuing fluid (and we do not see how this can be refused), the machine must be nearly twice as powerful. We therefore repeat our wonder, that it has not been brought into use. But it appears that no trial has been made even of a model; so that we have no experiments to encourage an engineer to repeat the trial. Even the late author Professor Segner has not related any thing of this kind in his *Exercitationes Hydraulicæ*, where he particularly describes the machine. This remissness probably has proceeded from fixing the attention on Euler's improved construction. It is plain that this must be a most cumbrous mass, even in a small size, requiring a prodigious vessel, and carrying an unwieldy load. If we examine the theory which recommends this construction, we find that the advantages, tho' real and sensible, bear but a small proportion to the whole performance of the simple machine as invented by Dr Barker. It is therefore to be regretted, that engineers have not attempted to realise the first project. We beg leave to recommend it, with an additional argument taken from an addition made to it by Mr Mathon de la Cour, in Rozier's *Journal de Physique*, January and August 1775. This gentleman brings down a large pipe FEH (fig. 13.) from a reservoir, bends it upward at H, and introduces it into two horizontal arms DA, DB, which have an upright spindle DK, carry-

Water-works.

Plate XLII.

ing

Water-works.

ing a millstone in the style of Dr Barker's mill. The ingenious mechanic will have no difficulty of contriving a method of joining these pipes, so as to permit a free circular motion without losing much water. The operation of the machine in this form is evident. The water, pressed by the column FG, flows out at the holes A and B, and the unbalanced pressure on the opposite sides of the arms forces them round. The compendiousness and other advantages of this construction are most striking, allowing us to make use of the greatest fall without any increase of the size of the machine. It undoubtedly enables us to employ a stream of water too scanty to be employed in any other form. The author gives the dimensions of an engine which he had seen at Bourg Argental. AB is 92 inches, and its diameter 3 inches; the diameter of each orifice is $1\frac{1}{8}$; FG is 21 feet; the pipe D was fitted into C by grinding; and the internal diameter of D is 2 inches.

When the machine was performing no work, or was unloaded, and emitted water by one hole only, it made 115 turns in a minute. This gives a velocity of 46 feet per second for the hole. This is a curious fact: For the water would issue from this hole at rest with the velocity of $37\frac{1}{2}$. This great velocity (which was much less than the velocity with which the water actually quitted the pipe) was undoubtedly produced by the prodigious centrifugal force, which was nearly 17 times the weight of the water in the orifice.

The empty machine weighed 80 pounds, and its weight was half supported by the upper pressure of the water, so that the friction of the pivots was much diminished. It is a pity that the author has given no account of any work done by the machine. Indeed it was only working ventilators for a large hall. His theory by no means embraces all its principles, nor is it well-founded.

We think that the free motion round the neck of the feeding pipe, without any loss of water or any considerable friction, may be obtained in the following manner: AB (fig. 14.) represents a portion of the revolving horizontal pipe, and CE *cc* part of the feeding pipe. The neck of the first is turned truly cylindrical, so as to turn easily, but without shake, in the collar C *c* of the feeding-pipe, and each has a shoulder which may support the other. That the friction of this joint may not be great, and the pipes destroy each other by wearing, the horizontal pipe has an iron spindle EF, fixed exactly in the axis of the joint, and resting with its pivot F in a step of hard steel, fixed to the iron bar GH, which goes across the feeding-pipe, and is firmly supported in it. This pipe is made bell-shaped, widening below. A collar or hose of thin leather is fitted to the inside of this pipe, and is represented (in section) by LKM *mkl*. This is kept in its place by means of a metal or wooden ring N *n*, thin at the upper edge, and taper shaped. This is drawn in above the leather, and stretches it, and causes it to apply to the side of the pipe all around. There can be no leakage at this joint, because the water will press the leather to the smooth metal pipe; nor can there be any sensible friction, because the water gets at the edge of the leather, and the whole unbalanced pressure is at the small crevice, between the two metal shoulders. These shoulders need not touch, so that the friction must be insensible. We imagine that this method of tightening a turning joint may be used with great advantage in many cases.

We have only further to observe on this engine, that any imperfection by which the passage of the water is diminished or obstructed produces a saving of water which is in exact proportion to the diminution of effect. The only inac-

curacy that is not thus compensated is when the jets are not at right angles to the arms.

We repeat our wishes, that engineers would endeavour to bring this machine into use, seeing many situations where it may be employed to great advantage. Suppose, for instance, a small supply of water from a great height applied in this manner to a centrifugal pump, or to a hair belt passing over a pulley, and dipping in the water of a deep well. This would be a hydraulic machine exceeding all others in simplicity and durability, though inferior in effect to some other constructions.

2. Of Undershot Wheels.

ALL wheels go by this name where the motion of the water is quicker than that of the partitions or boards of the wheel, and it therefore impels them. These are called the *float-boards*, or *floats*, of an undershot wheel. The water, running in a mill-row, with a velocity derived from a head of water, or from a declivity of channel, strikes on these floats, and occasions, by its deflections sidewise and upwards, a pressure on the floats sufficient for impelling the wheel.

There are few points of practical mechanics that have been more considered than the action of water on the floats of a wheel; hardly a book of mechanics being silent on the subject. But the generality of them, at least such as are intelligible to persons who are not very much conversant in dynamical and mathematical discussion, have hardly done any thing more than copied the earliest deductions from the simple theory of the resistance of fluids. The consequence has been, that our practical knowledge is very imperfect; and it is still chiefly from experience that we must learn the performance of undershot wheels. Unfortunately this stops their improvement; because those who have the only opportunities of making the experiments are not sufficiently acquainted with the principles of hydraulics, and are apt to ascribe differences in their performance to trifling nostrums in their construction, or in the manner of applying the impulse of the water.

We have said so much on the imperfection of our theories of the impulse of fluids in the article *RESISTANCE of Fluids*, that we need not repeat here the defects of the common explanations of the motions of undershot wheels. The part of this theory of the impulse of fluids which agrees best with observation is, *that the impulse is in the duplicate proportion of the velocity with which the water strikes the float*. That is, if *v* be the velocity of the stream, and *u* the velocity of the float, we shall have *F*, the impulse on the float when held fast to its impulse *f* on the float moving with the velocity *u*, as v^2 to $v-u^2$, and $f = F \times \frac{v-u^2}{v^2}$.

This is the pressure acting on the float, and urging the wheel round its axis. The wheel must yield to this motion, if the resistance of the work does not exert a superior pressure on the float in the opposite direction. By yielding, the float withdraws from the impulse, and this is therefore diminished. The wheel accelerates, the resistances increase, and the impulses diminish, till they become an exact balance for the resistances. The motion now remains uniform, and the momentum of impulse is equal to that of resistance. The performance of the mill therefore is determined by this; and, whatever be the construction of the mill, its performance is best when the momentum of impulse is greatest. This is had by multiplying the pressure on the float by its velocity. Therefore the momentum will be expressed by

$F \times \frac{v-u^2}{v^2} \times u$. But since *F* and v^2 are constant quanti-

ties, the momentum will be proportional to $v \times \frac{v}{v-u}$. Let x represent the relative velocity. Then $v-x$ will be $=v$, and the momentum will be proportional to $\frac{v-x}{v-x} \times x^2$, and will be a maximum when $v-x \times x^2$ is a maximum, or when $v x^2 - x^3$ is a maximum. This will be discovered by making its fluxion $=0$. That is,

$$2 v x x - 3 x^2 x = 0.$$

$$\text{and } 2 v x - 3 x^2 = 0$$

$$\text{or } 2 v - 3 x = 0$$

$$\text{and } 2 v = 3 x, \text{ and } x = \frac{2}{3} v; \text{ and therefore } v - x, \text{ or } v, = \frac{1}{3} v.$$

That is, the velocity of the float must be one third of the velocity of the stream. It only remains to say what is the absolute pressure on the float thus circumstanced. Let the velocity v be supposed to arise from the pressure of a head of water h . The common theory teaches that the impulse on a given surface S at rest is equal to the weight of a column $h S$; put this in place of F , and $\frac{2}{3} v$ in place of $v-u$ and $\frac{1}{3} v$ for u . This gives us $S h \times \frac{4}{27} v$ for the momentum. Now the power expended is $S h v$, or the column $S h$ moving with the velocity v . Therefore the greatest performance of an undershot wheel is equivalent to raising $\frac{4}{27}$ of the water that drives it to the same height.

But this is too small an estimation; for the pressure exerted on a plane surface, situated as the float of a mill-wheel, is considerably greater than the weight of the column $S h$. This is nearly the pressure on a surface wholly immersed in the fluid. But when a small vein strikes a larger plane, so as to be deflected on all sides in a thin sheet, the impulse is almost double of this. This is in some measure the case in a mill wheel. When the stream strikes it, it is heaped up along its face, and falls back again—and during this motion it is acting with a hydrostatic pressure on it. When the wheel dips into an open river, this accumulation is less remarkable, because much escapes laterally. But in a mill course it may be considerable.

We have considered only the action on one float, but several generally act at once. The impulse on most of them must be oblique, and is therefore less than when the same stream impinges perpendicularly; and this diminution of impulse is, by the common theory, in the proportion of the sine of the obliquity. For this reason it is maintained, that the impulse of the whole stream on the lowest float board, which is perpendicular to the stream, is equal to the sum of the impulses made on all the floats which then dip into the water; or that the impulse on any oblique float is precisely equal to the impulse which that part of the stream would have made on the lowest floatboard had it not been interrupted. Therefore it has been recommended to make such a number of floatboards, that when one of them is at the bottom of the wheel, and perpendicular to the stream, the next in succession should be just entering into the water. But since the impulse on a float by no means annihilates all the motion of the water, and it bends round it and hits the one behind with its remaining force, there must be some advantage gained by employing a greater number of floats than this rule will permit. This is abundantly confirmed by the experiments of Smeaton and Bossut. Mr Bossut formed three or four suppositions of the number of floats, and calculated the impulse on each; according to the observations made in a course of experiments made by the Academy of Sciences, and inserted by us in the article *RESISTANCE of Fluids*; and when he summed them up and compared the results with his experiments, he found the agreement very satisfactory. He deduces a general rule, that if the velocity of the wheel is $\frac{1}{3}$ of that of the stream, and if 72 degrees of the circumference are immersed in the stream, the wheel should have 36 floats. Each will dip $\frac{1}{3}$ th of the radius. The velocity being fill

supposed the same, there should be more or fewer floats according as the arch is less or greater than 72 degrees.

Such is the theory, and such are the circumstances which it leaves undetermined. The accumulation of the water on a floatboard, and the force with which it may still strike another, are too intricate to be assigned with any tolerable precision: For such reasons we must acknowledge that the theory of undershot wheels is still very imperfect, and that recourse must be had to experience for their improvement. We therefore strongly recommend the perusal of Mr Smeaton's experiments on undershot-wheels, contained in the same dissertation with those we have quoted on overshot-wheels. We have only to observe, that to an ordinary reader the experiments will appear too much in favour of undershot-wheels. His aim is partly to establish a theory, which will state the relation between their performance and the velocity of the stream, and partly to state the relation between the power expended and the work done. The velocity in his experiments is always considerably below that which a body would acquire by falling from the surface of the head of water; or it is the velocity acquired by a shorter fall. Therefore if we estimate the power expended by the quantity of water multiplied by this diminished fall, we shall make it too small; and the difference in some cases is very great: yet, even with these concessions, it appears that the utmost performance of an undershot wheel does not surpass the raising $\frac{1}{3}$ of the expended water to the place from which it came. It is therefore far inferior to an overshot wheel expending the same power; and Mr Belidor has led engineers into very mistaken maxims of construction, by saying that overshot wheels should be given up, even in the case of great falls, and that we should always bring on the water from a sluice in the very bottom of the dam, and bring it to the wheel with as great velocity as possible. Mr Smeaton also says, that the maximum takes place when the velocity of the wheel is $\frac{1}{3}$ ths of that of the stream, instead of $\frac{2}{3}$ ths according to the theory; and this agrees with the experiments of Bossut. But he measured the velocity by means of the quantity of water which run past. This must give a velocity somewhat too small; as will appear by attending to Buat's observations on the superficial, the mean, and the bottom velocities.

The rest of his observations, of which we have given an abstract in *MECHANICS*, Sect. V. are most judicious, and well adapted to the instruction of practitioners. We have only to add to them the observations of Deparcieux and Bossut, who have evinced, by very good experiments, that there is a very sensible advantage gained by inclining the floatboards to the radius of the wheel about 20 degrees, so that the lowest floatboard shall not be perpendicular, but have its point turned up the stream about 20 degrees. This inclination causes the water to heap up along the floatboard, and act by its weight. The floats should therefore be made much broader than the vein of water interrupted by them is deep.

Some engineers, observing the great superiority of overshot wheels above undershot wheels driven by the same expence of power, have proposed to bring the water home to the bottom of the wheel on an even bottom, and to make the floatboard no deeper than the aperture of the sluice, which would permit the water to run out. The wheel is to be fitted with a close sole and sides, exactly fitted to the end of this trough, so that if the wheel is at rest, the water may be dammed up by the sole and floatboard. It will therefore press forward the floatboard with the whole force of the head of water. But this cannot answer; for if we suppose no floatboards, the water will flow out at the bottom, propelled in the manner those persons suppose; and it will be supplied from be-

Water-works.

hind, the water coming *slowly* from all parts of the trough to the hole below the wheel. But now add the floats, and suppose the wheel in motion with the velocity that is expected. The other floats must drag into motion all the water which lies between them, giving to the greatest part of it a motion vastly greater than it would have taken in consequence of the pressure of the water behind it; and the water out of the reach of the floats will remain still, which it would not have done independent of the floatboards above it, because it would have contributed to the expence of the hole. The motion therefore which the wheel will acquire by this construction must be so different from what is expected, that we can hardly say what it will be.

We are therefore persuaded, that the best way of delivering the water on an undershot-wheel in a close mill course is, to let it slide down a very smooth channel, without touching the wheel till near the bottom, where the wheel should be exactly fitted to the course; or, to make the floats exceedingly broader than the depth of the vein of water which glides down the course, and allow it to be partly intercepted by the first floats, and heap up along them, acting by its weight, after its impulse has been expended. If the bottom of the course be an arch of a circle described with a radius much greater than that of the wheel, the water which slides down will be thus gradually intercepted by the floats.

Attempts have been made to construct water-wheels which receive the impulse obliquely, like the sails of a common wind-mill. This would, in many situations, be a very great acquisition. A very slow but deep river could in this manner be made to drive our mills; and although much power is lost by the obliquity of the impulse, the remainder may be very great. It is to be regretted, that these attempts have not been more zealously prosecuted; for we have no doubt of their success in a very serviceable degree. Engineers have been deterred, because when such wheels are plunged in an open stream, their lateral motion is too much impeded by the motion of the stream. We have seen one, however, which was very powerful: It was a long cylindrical frame, having a plate standing out from it about a foot broad, and surrounding it with a very oblique spiral like a cork-screw. This was plunged about $\frac{1}{4}$ th of its diameter (which was about 12 feet), having its axis in the direction of the stream. By the work which it was performing, it seemed more powerful than a common wheel which occupied the same *breadth* of the river. Its length was not less than 20 feet: it might have been twice as much, which would have doubled its power, without occupying more of the water-way. Perhaps such a spiral, continued to the very axis, and moving in a hollow canal wholly filled by the stream, might be a very advantageous way of employing a deep and slow stream.

But mills with oblique floats are most useful for employing small streams, which can be delivered from a spout with a great velocity. Mr Bosjut has considered these with due attention, and ascertained the best modes of construction. There are two which have nearly equal performances: 1. The vanes being placed like those of a wind-mill, round the rim of a horizontal or vertical wheel, and being made much broader than the vein of water which is to strike them, let the spout be so directed that the vein may strike them perpendicularly. By this measure it will be spread about on the vane in a thin sheet, and exert a pressure nearly equal to twice the weight of a column whose base is the orifice of the spout, and whose height is the fall producing the velocity.

Mills of this kind are much in use in the south of Europe. The wheel is horizontal, and the vertical axis carries the millstone; so that the mill is of the utmost simplicity:

and this is its chief recommendation; for its power is greatly inferior to that of a wheel constructed in the usual manner.

2. The vanes may be arranged round the rim of the wheel, not like the sails of a wind-mill, but in planes inclined to the radii, but parallel to the axis, or to the planes passing through the axis. They may either stand on a sole, like the oblique floats recommended by De Parceux, as above mentioned; or they may stand on the side of the rim, not pointing to the axis, but aside from it.

This disposition will admit the spout to be more conveniently disposed either for a horizontal or a vertical wheel.

We shall conclude this article by describing a contrivance of Mr Burns, the inventor of the double bucketed wheel, for fixing the arms of a water-wheel. It is well known to mill-wrights that the method of fixing them by making them to pass through the axle, weakens it exceedingly, and by lodging water in the joint, soon causes it to rot and fail. They have, therefore, of late years put cast-iron flanches on the axis, to which each arm is bolted: or the flanches are so fashioned as to form boxes, serving as mortises to receive the ends of the arms. These answer the purpose completely, but are very expensive; and it is found that arms of fir, bolted into flanches of iron, are apt to work loose. Mr Burns has made wooden flanches of a very curious construction, which are equally firm, and cost much less than the iron ones.

This flanch consists of eight pieces, four of which compose the ring represented in fig. 15. meeting in the joints ab, ab, ab, ab , directed to the centre O . The other four are covered by these, and their joints are represented by the dotted lines $\alpha\beta, \alpha\beta, \alpha\beta, \alpha\beta$. These two rings break joint in such a manner that an arm MN is contained between the two nearest joints $a'b'$ of the one, and $\alpha'\beta'$ of the other. The tenon formed on the end of the arm A , &c. is of a particular shape: one side, GF , is directed to the centre O ; the other side, $BCDE$, has a small shoulder BC ; then a long side CD directed to the centre O ; and then a third part DE parallel to GF , or rather diverging a little from it, so as to make up at E the thickness of the shoulder BC ; that is, a line from B to E would be parallel to CD . This side of the tenon fits exactly to the corresponding side of the mortise; but the mortise is wider on the other side, leaving a space $GFKb$ a little narrower at FK than at Gb . These tenons and mortises are made extremely true to the square; the pieces are put round the axle, with a few blocks or wedges of soft wood put between them and the axle, leaving the space empty opposite to the place of each arm, and firmly bolted together by bolts between the arm-mortises. The arms are then put in, and each is pressed home to the side CDE , and a wedge HF of hard wood is then put into the empty part of the mortise and driven home. When it comes through the flanch and touches the axle, the part which has come through is cut off with a thin chisel, and the wedge is driven better home. The spaces under the ends of the arms are now filled with wedges, which are driven home from opposite sides, till the circle of the arms stands quite perpendicular on the axle, and all is fast. It needs no hoops to keep it together, for the wedging it up round the axle makes the two half rings draw close on the arms, and it cannot start at its own joints till it crushes the arms. Hoops, however, can do no harm, when all is once wedged up, but it would be improper to put them on before this be done. For the account of another very curious hydraulic machine, see ZURICH.

WORMS, an ancient, large, and famous city of Germany, in the palatinate of the Rhine, with a bishop's see, whose bishop is a sovereign and prince of the empire. It is a free and imperial city, and the inhabitants are Protestants. In the war of 1689 it was taken by the French, who almost reduced it to ashes.—The bishop afterwards built a new palace in it; and it is famous for a diet held here in 1521, at which Luther assailed in person. The Protestants have lately built a handsome church, where Luther is represented as appearing at the diet. It is noted for the excellent wine that grows in the neighbourhood, which they call *our Lady's milk*. In the campaign of 1742, king Geo. II. took up his quarters in this city, and lodged at the bishop's palace after the battle of Dettingen. It is seated on the western bank of the Rhine, 14 miles north-west of Heidelberg, 25 south east of Mentz, and 32 south-west of Frankfurt. *V. Long.* 8. 29. *N. Lat.* 49. 32.

WORMING OF DOGS. All spaniels have certain strings under their tongues, by most called a *worm*; this must be taken out when they are about two months old, with the help of a sharp knife to slit it, and a shoemaker's awl to raise it up; you must be careful to take all out, or else your pains is to little purpose; for till then he will be hardly ever fat and right, in regard the worm or string will grow foul and troublesome, and hinder his rest and eating. This operation is generally recommended as a preventive of madness in dogs, or at least as disabling them, if mad, from biting in that condition.

WORMIUS (Olaus), a learned Danish physician, born in 1584 at Arhusen in Jutland. After beginning his studies at home, he studied at several foreign universities, and travelled to various parts of Europe for improvement. He returned to his native country in 1613, and was made professor of the belles lettres in the university of Copenhagen. In 1615, he was translated to the chair of the Greek professor; and in 1624 to the professorship of physic, which he held to his death. These occupations did not hinder him from practising in his profession, and from being the fashionable physician: the king and court of Denmark always employed him; and Christian IV. as a recompense for his services, conferred on him a canonry of Lundon. He published some pieces on subjects relating to his profession, several works in defence of Aristotle's philosophy, and several concerning the antiquities of Denmark and Norway; for which latter he is principally regarded, as they are very learned, and contain many curious particulars. He died in 1654.

WORMWOOD, in botany. See **ARTEMISIA**.

WORSHIP OF GOD (*cultus Dei*), amounts to the same with what we otherwise call *religion*. This worship consists in paying a due respect, veneration, and homage to the Deity, under a certain expectation of reward. And this internal respect, &c. is to be shown and testified by external acts; as prayers, sacrifices, thanksgivings, &c.

The Quietists, and some other mystic divines, set aside not only all use of external worship, but even the consideration of rewards and punishments. Yet even the Lutherans had a notion that God did not require us to leave him for nought: "Dū quā obrem colendi sūt (says Cicero), non intelligo, nullo nec accepto ab illis nec sperato bono."

The school divines divide worship into divers kinds, *viz.* *lutria*, that rendered to God; and *idololatrit*, that rendered to idols or images. To which the Romanists add, *devotio*, that rendered to saints; and *hyperdulia*, that to the Virgin. Some theological writers have observed, that the Greek word, *προσκυνησις*, *to worship*, is not descriptive only of the honour which is appropriated to God, but is indifferently used to signify the honour and respect which are paid to superiors of all kinds in heaven or on earth. Accordingly, they have distinguished between civil and religious worship.

That it is the duty of man to worship his Maker, has been sufficiently proved under other articles (see **PRAYER**; and **THEOLOGY**, n^o 45—45.). It is not indeed easily to be conceived how any one who has tolerably just notions of the attributes and providence of God, can possibly neglect the duty of *private* worship; and though we have admitted in the last of the two articles referred to, that *public* worship does not seem to be enjoined in that system which is called the religion of *nature*, yet it is most expressly commanded by the religion of **CHRIST**, and will be regularly performed by every one who reflects on its great utility.

As the illiterate vulgar cannot form to themselves correct notions of the divine providence and attributes, it is obvious, that without the institution of public worship, they would never think of worshipping God at all, unless perhaps occasionally, when under the pressure of some severe calamity; but occasional worship, the offspring of compulsion, could have little of the resigned spirit of true devotion. Ignorant, however, as the lowest of the vulgar are, and necessarily must be, it cannot be denied, that in most Christian countries, perhaps in all, they are more accurately acquainted with the first principles of religion, and the laws of morality, than even the leaders of barbarous nations. This superiority is doubtless owing in some measure to their access to the Sacred Scriptures, but much more, we are persuaded, to the instruction which they receive in the assemblies which they frequent for public worship. If this be admitted, public worship may be easily proved to be the duty of every individual of the community: For were those, who may be supposed to stand in no need either of the contagion of society to kindle their own devotion, or of the preaching of a clergyman to instruct them in the doctrines and precepts of the gospel, to forsake, on these accounts, the assembling themselves together, as the manner of some is, religious assemblies and public worship would very quickly fall into universal disuse. Man is an animal prone to imitation; and every order in society is ambitious of treading in the footsteps of the order immediately above it. Were the wife and the good, therefore, permitted to absent themselves from the assemblies instituted for the public worship of the Creator and Redeemer of the world, others would quickly follow their example; impelled to it not only by this universal propensity, but by the additional motive of wishing to appear both to the world and to themselves as wise and as good as their privileged neighbours. The consequence is obvious: one man would stay from church with the serious intention perhaps of employing the Lord's day in private devotion and religious study; another, following his example, would absent himself upon the same pretence, but would in reality

Worship.

Worship
||
Wotton.

waste the day in dozing indolence or in secret sensuality. For these and other reasons which might be easily assigned, no sincere Christian will think himself at liberty to dispute a practice enjoined by the inspired preachers of his religion, coeval with the institution, and retained by every sect into which it has since been unhappily divided.

As Christian worship consists of prayers and praises, it has been a matter of some debate whether it is most properly performed by preconcerted forms or liturgies, or by extemporaneous addresses to the Almighty. Both these modes have their advantages and disadvantages; and by the sacred writers neither of them is prescribed in opposition to the other.

The advantages of a liturgy are, that it prevents absurd, extravagant, or impious addresses to God, which the folly or enthusiasm of individuals must always be in danger of producing; it gives the congregation an opportunity of joining in the prayers which are put up for them, which they cannot possibly do in a series of extemporaneous petitions, since before they can assent to any one of these and make it their own, their attention is necessarily called away to that which succeeds it; and it relieves the clergyman from the labour of composition, which seems incompatible with that fervour which constitutes the spirit of devotion.

The disadvantages of a fixed liturgy, which are the recommendations of extemporary prayer, are principally two. The forms composed in one age must, by the unavoidable change of language, circumstances, and opinions, become in some degree unfit for another; and the perpetual repetition of the same form of words is very apt to produce inattentive lassitude in the congregation. Would the clergy of the church of England take that liberty which is allowed them in the bidding prayer before sermon, perhaps the service of that church would unite in itself all the advantages both of liturgic and extemporary worship. We have only to add on this subject, that public prayers, whether precomposed or not, ought to be compendious; that they ought to express just conceptions of the Divine attributes; recite such wants as the congregation are likely to feel and no other; that they ought to contain as few controverted propositions as possible; and that, if it can be done without offence, the pompous style of *the flute* should be laid aside in our prayers for the king and all that are in authority; because in every act which carries the mind to God, human greatness must be annihilated.

WORT, the infusion of malt, of which beer is made. The uses of this infusion in common affairs are well known. By Dr M^r Bride it has lately been found to have a strong antiseptic virtue, and to be useful in preventing the scurvy and other diseases to which sailors are liable; which was confirmed by captain Cook in his late voyages. See *Means of Preserving the Health of SEAMEN*.

WOTTON (Sir Henry), an eminent writer, was the son of Thomas Wotton, Esq; and was born in 1568. He studied for some time at New-college, Oxford, whence he removed to Queen's-college, where he made a great progress in logic and philosophy; wrote a tragedy for the use of that college, called *Tancredo*; and afterwards received the degree of master of arts. After this, leaving the university, he travelled into France, Germany, and Italy; and having spent about nine years abroad, he returned to England, and became secretary to Robert earl of Essex, with whom he continued till that earl was apprehended for high-treason. He then retired to Florence, where he became known to the grand duke of Tuscany, who sent him privately with letters to James VI. king of Scotland, under the name of *Osavio Baldi*, to inform that king of a design

against his life. Some months after he went back to Florence; but king James coming to the possession of the crown of England, Mr Wotton returned home, was knighted by his majesty, and sent ambassador to the republic of Venice; and afterwards was employed in many other embassies to that and other courts; but the only reward he obtained for these services was his having the provostship of Eton conferred upon him about the year 1623, which he kept till his death, which happened in 1639. After his decease some of his manuscripts and printed tracts were published together in a volume, intitled, *Reliquie Wottonianæ*.

WOTTON (Dr William), a very learned divine and writer, was the son of Mr Henry Wotton, B. D. rector of Wrentham, in Suffolk, where he was born in 1666. He was educated by his father, a gentleman well skilled in the learned languages: under whom he made such amazing proficiency, that at five years of age it is said he could render several chapters in the gospels out of Latin and Greek, and many psalms in Hebrew, into his mother tongue. When he was very young, he remembered the whole of almost every discourse he had heard, and often surprised a preacher by repeating his sermons to him. He was admitted into Catharine-hall in Cambridge some months before he was ten years old; when the progress he made in learning in that university engaged Dr Dupont, then master of Magdalen college, and dean of Peterborough, to write an elegant copy of Latin verses in his praise. In 1679 he took the degree of bachelor of arts when he was but twelve years and five months old; and the winter following he was invited to London by Dr Gilbert Burnet, then preacher at the Rolls, who introduced him to most of the learned men in that city, and particularly to Dr William Lloyd, bishop of St Asaph; to whom he recommended himself by repeating to him one of his sermons, as Dr Burnet had engaged he should. In 1691 he commenced bachelor of divinity. The same year bishop Lloyd gave him the sinecure of Llandrillo, in Denbighshire. He was afterwards made chaplain to the earl of Nottingham, then secretary of state, who presented him to the rectory of Middleton Keynes, in Bucks, and to whom he dedicated his *Reflections upon Ancient and Modern Learning*. In 1705, bishop Burnet gave him a prebend in the church of Salisbury; and in 1707, archbishop Tenison presented him with the degree of doctor of divinity: but in 1714, the difficulties he laboured under with respect to his private fortune, obliged him to retire into South Wales, where he was treated with great kindness and humanity by the gentlemen of that country; and wrote there the "Memoirs of the Cathedral Churches of St David's and Landaff," and his "Miscellaneous Discourses relating to the Traditions and Usages of the Scribes and Pharisees;" which were afterwards printed. He died in 1726. This great man was remarkable for his humanity and friendliness of temper; the narrowness of a party spirit never broke in upon any of his friendships; and his time and abilities were at the service of any person who was making advances in real learning. He wrote, besides the above works, 1. A History of Rome. 2. A Defence of his Reflections upon Ancient and Modern Learning. 3. A Discourse concerning the Languages of Babel. 4. Advice to a young Student, with a Method of Study for the first four Years; and other learned pieces.

WRASSE, or old wife, in ichthyology. See LABRUS.

WREATH, in heraldry, a roll of fine linen or silk (like that of a Turkish turban), consisting of the colours born in the escutcheon, placed in an achievement between the

the helmet and the crest, and immediately supporting the crest.

WRECK, or SHIPWRECK, the destruction of a ship by rocks or shallows at sea.

By the ancient common law, where any ship was lost at sea, and the goods or cargo were thrown upon the land, these goods, so wrecked, were judged to belong to the king: for it was held, that, by the loss of the ship, all property was gone out of the original owner. But this was undoubtedly adding sorrow to sorrow, and was consonant neither to reason nor humanity. Wherefore it was first ordained by king Henry I. that if any person escaped alive out of the ship, it should be no wreck; and afterwards king Henry II. by his charter, declared, that if on the coasts of either England, Poitou, Oleron, or Gascony, any ship should be distressed, and either man or beast should escape or be found therein alive, the goods should remain to the owners, if they claimed them within three months; but otherwise should be esteemed a wreck, and should belong to the king, or other lord of the franchise. This was again confirmed with improvements by king Richard I.; who, in the second year of his reign, not only established these concessions, by ordaining that the owner, if he was shipwrecked and escaped, *omnes res suas liberas, et quietas haberet*, but also, that if he perished, his children, or in default of them, his brethren and sisters, should retain the property; and in default of brother or sister, then the goods should remain to the king (A). And the law, as laid down by Bracton in the reign of Henry III. seems still to have improved in its equity. For then, if not only a dog (for instance) escaped, by which the owner might be discovered, but if any certain mark were set on the goods, by which they might be known again, it was held to be no wreck. And this is certainly most agreeable to reason; the rational claim of the king being only founded upon this, that the true owner cannot be ascertained. Afterwards, in the first statute of Westminster, the time of limitation of claims, given by the charter of Henry II. is extended to a year and a day, according to the usage of Normandy: and it enacts, that if any man, a dog, or a cat, escape alive, the vessel shall not be adjudged a wreck. These animals, as in Bracton, are only put for examples; for it is now held, that not only if any live thing escape, but if proof can be made of the property of any of the goods or lading which come to shore, they shall not be forfeited as wreck. The statute further ordains, that the sheriff of the county shall be bound to keep the goods a year and a day (as in France for one year, agreeable to the maritime laws of Oleron, and in Holland for a year and a half), that if any man can prove a property in them, either in his own right or by right of representation, they shall be restored to him without delay; but if no such property be proved within that time, they then shall be the king's. If the goods are of a perishable nature, the sheriff may sell them, and the money shall be liable in their stead. This revenue of wrecks is frequently granted out to lords of manors as a royal franchise; and if any one be thus intitled to wrecks in his own land, and the king's goods are wrecked thereon, the king may claim them at any time, even after the year and day.

It is to be observed, that, in order to constitute a legal wreck, the goods must come to land. If they continue at

sea, the law distinguishes them by the barbarous and uncouth appellations of *jetsam*, *flotsam*, and *ligan*. *Jetsam* is where goods are cast into the sea, and there sink and remain under water: *flotsam* is where they continue swimming on the surface of the waves: *ligan* is where they are sunk in the sea, but tied to a cork or buoy, in order to be found again. These are also the king's, if no owner appears to claim them; but if any owner appears, he is intitled to recover the possession. For even if they be cast overboard, without any mark or buoy, in order to lighten the ship, the owner is not by this act of necessity construed to have renounced his property: much less can things *ligan* be supposed to be abandoned, since the owner has done all in his power to assert and retain his property. These three are therefore accounted for far a distinct thing from the former, that by the king's grant to a man of wrecks, things *jetsam*, *flotsam*, and *ligan*, will not pass.

Wrecks, in their legal acceptation, are at present not very frequent: for if any goods come to land, it rarely happens, since the improvement of commerce, navigation, and correspondence, that the owner is not able to assert his property within the year and day limited by law. And in order to preserve this property entire for him, and if possible to prevent wrecks at all, our laws have made many very humane regulations; in a spirit quite opposite to those savage laws which formerly prevailed in all the northern regions of Europe, and a few years ago were still said to subsist on the coasts of the Baltic Sea, permitting the inhabitants to seize on whatever they could get as lawful prize; or, as an author of their own expresses it, "*in naufragorum miseria et calamitate tanquam vultures ad prædam currere.*" For by the statute 27 Edw. III. c. 13. if any ship be lost on the shore, and the goods come to land (which cannot, says the statute, be called *wreck*), they shall be presently delivered to the merchants, paying only a reasonable reward to those that saved and preserved them, which is intitled *salvage*. Also by the common law, if any persons (other than the sheriff) take any goods so cast on shore, which are not legal wreck, the owners might have a commission to inquire and find them out, and compel them to make restitution. And by 12 Ann. II. 2. c. 18. confirmed by 4 Geo. I. c. 12. in order to assist the distressed, and prevent the scandalous illegal practices on some of our sea-coasts (too similar to those on the Baltic), it is enacted, that all head-officers and others of towns near the sea, shall, upon application made to them, summon as many hands as are necessary, and send them to the relief of any ship in distress, on forfeiture of L. 100; and in case of assistance given, salvage shall be paid by the owners, to be assessed by three neighbouring justices. All persons that secretly any goods shall forfeit their treble value: and if they wilfully do any act whereby the ship is lost or destroyed, by making holes in her, stealing her pumps, or otherwise, they are guilty of felony without benefit of clergy. Lastly, by the statute 26 Geo. II. c. 19. plundering any vessel, either in distress or wrecked, and whether any living creature be on board or not (for whether wreck or otherwise, it is clearly not the property of the populace), such plundering or preventing the escape of any person that endeavours to save his life, or wounding him with intent to destroy him, or putting out false lights in order to bring any vessel into danger, are all declared to be capital felonies; in like manner as the destroying of trees, steeples,

Wreck.

(A) In like manner Constantine the Great, finding that by the imperial law the revenue of wrecks was given to the prince's treasury or fiscus, restrained it by an edict (Cod. 11. 5. 1.) and ordered them to remain to the owners; adding this humane expostulation: "Quod enim jus habet fiscus in aliena calamitate, ut de re tam lucrosa compendium sectetur?"

Wier,
Wrestling.

er other stated sea-marks, is punished by the statute 3 Eliz. c. 13. with a forfeiture of L. 100 or outlawry. Moreover, by the statute of Geo. II. pilfering any goods cast ashore is declared to be petty larceny; and many other salutary regulations are made, for the more effectually preserving ships of any nation in distress.

By the civil law, to destroy persons shipwrecked, or prevent their saving the ship, is capital. And to steal even a plank from a vessel in distress or wrecked, makes the party liable to answer for the whole ship and cargo. The laws also of the Wisigoths, and the most early Neapolitan constitutions, punished with the utmost severity all those who neglected to assist any ship in distress, or plundered any goods cast on shore.

WREN, in ornithology. See MOTACILLA.

WREN (sir Christopher), a great philosopher, and one of the most learned and most eminent architects of his age, was the son of Christopher Wren dean of Windsor, and was born in 1632. He studied at Wadham college in Oxford; where he took the degree of master of arts in 1653, and was chosen fellow of All Souls college. When very young he discovered a surprizing genius for the mathematics; in which science he made great advances before he was sixteen years old. In 1657, he was made professor of astronomy at Gresham college, London; which he resigned in 1660, on his being chosen to the Savilian professorship of astronomy in Oxford: he was the next year created doctor of laws, and in 1663 was elected fellow of the Royal Society. He was one of the commissioners for the reparation of St Paul's; and in 1665 travelled into France, to examine the most beautiful edifices there, when he made many curious observations. At his return to England, he drew a noble plan for rebuilding the city of London after the fire, which he presented to parliament; and upon the decease of Sir John Denham in 1668, was made surveyor-general of his majesty's works; and from that time had the direction of a great number of public edifices, by which he acquired the highest reputation. He built the magnificent theatre at Oxford, St Paul's cathedral, the churches of St Stephen Walbrook, and St Mary-le-Bow, the Monument, the modern part of the palace of Hampton Court, Chelsea College, one of the wings of Greenwich Hospital, and many other beautiful edifices. He was president of the Royal Society, one of the commissioners of Chelsea College, and twice member of parliament; first for Plymouth in Devonshire, and then for Melcomb Regis in the same county; but in 1718 was removed from his place of surveyor-general. He died in 1723, and was interred in the vault under St Paul's.

This great man also distinguished himself by many curious inventions and discoveries in natural philosophy; and, among many others, contrived an instrument for measuring the quantity of rain that falls on any space of land for a year; he invented many ways of making astronomical observations more accurate and easy; and was the first author of the anatomical experiment of injecting liquors into the veins of animals, &c. He translated into Latin Mr Oughtred's *Horologigraphica Geometrica*; and wrote a Survey of the cathedral church of Salisbury, and other pieces. After his death his posthumous works and draughts were published by his son.

WRESTLING, a kind of combat or engagement between two persons unarmed, body to body, to prove their strength and dexterity, and try which can throw his opponent to the ground.

Wrestling is an exercise of very great antiquity and fame. It was in use in the heroic age; witness Hercules, who wrestled with Antæus.

It continued a long time in the highest repute, and had

considerable rewards and honours assigned to it at the Olympic games. It was the custom for the Athletæ to anoint their bodies with oil, to give the less hold to their antagonists.

Lycurgus ordered the Spartan maids to wrestle in public quite naked, in order, as it is observed, to break them of their too much delicacy and niceness, to make them appear more robust, and to familiarize the people, &c. to such nudities.

WRIST, in ANATOMY. See there, n^o 53.

WRIT, in law, signifies, in general, the king's precept in writing under seal, issuing out of some court, directed to the sheriff or other officer, and commanding something to be done in relation to a suit or action, or giving commission to have the same done. And, according to Fitzherbert, a writ is said to be a formal letter of the king in parchment, sealed with his seal, and directed to some judge, officer, or minister, &c. at the suit of a subject, for the cause briefly expressed, which is to be determined in the proper court according to law.

WRITS, in civil actions, are either original or judicial: original, are such as are issued out of the court of chancery for the summoning of a defendant to appear, and are granted before the suit is commenced, in order to begin the same; and judicial writs issue out of the court where the original is returned, after the suit is begun. See PROCESS.

The original writ is the foundation of the suit. See SUIT.

When a person hath received an injury, and thinks it worth his while to demand a satisfaction for it, he is to consider with himself, or take advice, what redress the law has given for that injury; and thereupon is to make application or suit to the crown, the fountain of all justice, for that particular specific remedy which he is determined or advised to pursue. As for money due on bond, an action of debt; for goods detained without force, an action of *detinue* or *trover*; or, if taken with force, an action of *trespass vi et armis*; or, to try the title of lands, a writ of entry or action of trespass in ejectment; or for any consequential injury received, a special action on the case. To this end he is to sue out, or purchase by paying the stated fees, an *original* or original writ, from the court of chancery, which is the *officina justitie*, the shop or mint of justice, wherein all the king's writs are framed. It is a mandatory letter from the king in parchment, sealed with his great seal, and directed to the sheriff of the county wherein the injury is committed, or supposed so to be, requiring him to command the wrongdoer or party accused, either to do justice to the complainant, or else to appear in court, and answer the accusation against him. Whatever the sheriff does in pursuance of this writ, he must return or certify to the court of common-pleas, together with the writ itself: which is the foundation of the jurisdiction of that court, being the king's warrant for the judges to proceed to the determination of the cause. For it was a maxim introduced by the Normans, that there should be no proceedings in common-pleas before the king's justices without his original writ; because they held it unfit that those justices, being only the substitutes of the crown, should take cognizance of any thing but what was thus expressly referred to their judgment. However, in small actions, below the value of forty shillings, which are brought in the court-baron or county-court, no royal writ is necessary; but the foundation of such suits continue to be (as in the times of the Saxons), not by original writ, but by plaint; that is, by a private memorial tendered in open court to the judge, wherein the party injured sets forth his cause of action: and the judge is bound of common right to administer justice therein, without any special mandate from the king. Now indeed even the royal writs are held to be demandable of common right, on paying the usual fees: for any

any delay in the granting them, or setting an unusual or exorbitant price upon them, would be a breach of magna charta, c. 29 "nulli vendemus, nulli negabimus, aut differemus justitiam vel rectum."

Original writs are either optional or peremptory; or, in the language of our law, they are either a *præcipe*, or a *fi se fecerit securum*. The *præcipe* is in the alternative, commanding the defendant to do the thing required, or show the reason wherefore he hath not done it. The use of this writ is where something certain is demanded by the plaintiff, which is in the power of the defendant himself to perform; as, to restore the possession of land, to pay a certain liquidated debt, to perform a specific covenant, to render an account, and the like; in all which cases the writ is drawn up in the form of a *præcipe* or command, to do thus, or show cause to the contrary; giving the defendant his choice to redress the injury or stand the suit. The other species of original writs is called a *fi se fecerit te securum*, from the words of the writ; which directs the sheriff to cause the defendant to appear in court, without any option given him, provided the plaintiff gives the sheriff security effectually to prosecute his claim. This writ is in use where nothing is specifically demanded, but only a satisfaction in general; to obtain which, and minister complete redress, the intervention of some judicature is necessary. Such are writs of trespass, or on the case, wherein no debt or other specific thing is sued for in certain, but only damages to be assessed by a jury. For this end the defendant is immediately called upon to appear in court, provided the plaintiff gives good security of prosecuting his claim. Both species of writs are telled, or witnessed, in the king's own name; "witness ourself at Westminster," or wherever the chancery may be held.

The security here spoken of, to be given by the plaintiff for prosecuting his claim, is common to both writs, though it gives denomination only to the latter. The whole of it is at present become a mere matter of form; and John Doe and Richard Roe are always returned as the standing pledges for this purpose.—The ancient use of them was to answer for the plaintiff, who in case he brought an action without cause, or failed in the prosecution of it when brought, was liable to an amercement from the crown for raising a false accusation; and so the form of the judgment still is. In like manner, as by the Gothic constitutions no person was permitted to lay a complaint against another, *nisi sub scriptura aut specificatione trium testium, quod actionem vellet persequi*; and, as by the laws of Sancho I. king of Portugal, damages were given against a plaintiff who prosecuted a groundless action.

The day on which the defendant is ordered to appear in court, and on which the sheriff is to bring in the writ, and report how far he has obeyed it, is called the *return of the writ*; it being then returned by him to the king's justices at Westminster. And it is always made returnable at the distance of at least 15 days from the date or test, that the defendant may have time to come up to Westminster, even from the most remote parts of the kingdom; and upon some day in one of the four terms, in which the court sits for the dispatch of business.

WRITING, the art or act of signifying and conveying our ideas to others, by letters or characters visible to the eye. See COMPOSITION, GRAMMAR, and LANGUAGE.

The most ancient remains of writing, which have been transmitted to us, are upon hard substances, such as stones and metals, which were used by the ancients for edicts and matters of public notoriety; the decalogue was written on two tables of stone; but this practice was not peculiar to the Jews, for it was used by most of the eastern nations, as well as by the Greeks and Romans; and therefore the ri-

dicals which Voltaire attempts to cast upon that part of the book of Genesis, where the people are commanded to write the law on stones, is absurd; for what is there said by no means implies, that other materials might not be used on common occasions. The laws penal, civil, and ceremonial, among the Greeks, were engraven on tables of brass, which were called *Cyberes*.

We find that wood was also used for writing on in different countries. In the Siamian library (N^o 43. 2.) are six specimens of Kufic writing, on boards about two feet in length, and six inches in depth. The Chinese, before the invention of paper, wrote or engraved with an iron tool upon thin board or on bamboo. Piny says, that table books of wood were in use before the time of Homer. These table books were called by the Romans *paganæ*. The wood was cut into thin slices, and finely planed and polished. The writing was at first upon the bare wood, with an iron instrument called a *style*. In later times these tables were usually waxed over, and written upon with that instrument. The matter written upon the tables which were thus waxed over was easily effaced, and by smoothing the wax new matter might be substituted in the place of what had been written before. The Greeks and Romans continued the use of waxed table-books long after the use of papyrus, leaves, and skins, became common, because they were so convenient for correcting extemporary compositions.

Table books of ivory are still used for memorandums, but they are commonly written upon with black lead pencils. The practice of writing on table books covered with wax was not entirely laid aside till the commencement of the 14th century.

The bark of trees was also used for writing by the ancients, and is so still in several parts of Asia. The same thing may be said of the leaves of trees. It is needless to observe the use of parchment and vellum, papyrus and paper, for writing; it is too well known. The method of fabricating these substances has been already described as they occurred in the order of the alphabet.

It is obvious, that when men wrote, or rather engraved, on hard substances, instruments of metal were necessary, such as the chisel and the stylus; but the latter was chiefly used for writing upon boards, waxed tablets, or on bark.

When the ancients wrote on softer materials than wood or metal, other instruments were used for writing with, of which reeds and canes seem to have been the first. Reeds and canes are still used as instruments for writing with by the Tartars, the Indians, the Persians, the Turks, and the Greeks. Pencils made of hair are used by the Chinese for their writing; they first liquify their ink, and dip their pencils into it. Hair-pencils have likewise been used for writing in Europe. Large capital letters were made with them from the time of the Roman emperors till the 16th century. After the invention of printing they were drawn by the illuminators. Quills of geese, swans, peacocks, crows, and other birds, have been used in these western parts for writing with, but how long is not easy to ascertain. St Isidore of Seville, who lived about the middle of the 7th century, describes a pen made of a quill as used in his time.

Method of restoring decayed WRITINGS. In the 77th vol. of the Phil. Trans. there is a paper on this subject by Sir Charles Blagden. One of the best methods he found upon experiment to be, covering the letters with phlogisticated or prussic alkali, with the addition of a diluted mineral acid; upon the application of which, the letters changed very speedily to a deep blue colour, of great beauty and intensity. To prevent the spreading of the colour, which, by blotting the parchment, detracts greatly from the legibility, the alkali should be put on first, and the diluted acid added upon it.

The

Writings
||
Wurtem-
berg.

The method found to answer best has been, to spread the alkali thin with a feather over the traces of the letters, and then to touch it gently, as nearly upon or over the letters as can be done with the diluted acid, by means of a feather or a bit of stick cut to a blunt point. Though the alkali should occasion no sensible change of colour, yet the moment the acid comes upon it, every trace of a letter turns at once to a fine blue, which soon acquires its full intensity, and is beyond comparison stronger than the colour of the original trace had been. If, then, the corner of a bit of blotting paper be carefully and dexterously applied near the letters, so as to imbibe the superfluous liquor, the staining of the parchment may be in a great measure avoided: for it is this superfluous liquor which, absorbing part of the colouring matter from the letters, becomes a dye to whatever it touches. Care must be taken not to bring the blotting paper in contact with the letters, because the colouring matter is soft whilst wet, and may easily be rubbed off. The acid chiefly employed was the marine; but both the vitriolic and nitrous succeed very well. They should be so far diluted as not to be in danger of corroding the parchment, after which the degree of strength does not seem to be a matter of much nicety.

Method of Copying WRITINGS. The ingenious Mr Watt, about 16 years ago, invented a method of copying writings very speedily, and without the possibility of committing mistakes. A piece of thin unsized paper is to be taken exactly of the size of the paper to be copied; it is to be moistened with water, or, what is better, with the following liquid: Take of distilled vinegar two pounds weight, dissolve it in one ounce of boracic acid; then take four ounces of oyster-shells calcined to whiteness, and carefully freed from their brown crust; put them into the vinegar, shake the mixture frequently for 24 hours, then let it stand until it deposits its sediment; filter the clear part through unsized paper into a glass vessel; then add two ounces of the best blue Aleppo galls bruised, and place the liquor in a warm place, shaking it frequently for 24 hours; then filter the liquor again through unsized paper, and add to it after filtration one quart, ale measure, of pure water. It must then stand 24 hours, and be filtered again if it shows a disposition to deposit any sediment, which it generally does. When the paper has been wet with this liquid, put it between two thick unsized papers to absorb the superfluous moisture; then lay it over the writing to be copied, and put a piece of clean writing paper above it. Put the whole on the board of a rolling-press, and press them thro' the rolls, as is done in printing copperplates, and a copy of the writing shall appear on both sides of the thin moistened paper; on one side in a reversed order and direction, but on the other side in the natural order and direction of the lines.

WRITTEN MOUNTAINS. See MOUNTAINS.

WRY-NECK, in ornithology. See JYNX.

WURTEMBERG, or WIRTEMBERG, a sovereign duchy of Germany, in Suabia; bounded on the north by Franconia, the archbishopric of Mentz, and the palatinate of the Rhine; on the east by the county of Oeting, the marquisate of Burgau, and the territory of Ulm; on the south by the principality of Hoen-Zollern, Furstenburg, and the marquisate of Hohenburg; and on the west by the palatinate of the Rhine, the marquisate of Baden, and the Black Forest. It is 65 miles in length, and as much in breadth, and the river Neckar runs almost through the middle of it from south to north. Though there are many mountains and woods, yet it is one of the most populous and fertile countries in Germany, producing plenty of grass, corn, fruits, and a great deal of wine towards the confines of the palati-

nate. There are also mines, and salt springs, with plenty of game and fish. It contains 645 villages, 88 towns, and 26 cities, of which Stutgard is the capital.

WURTSBURG, a large bishopric in Germany, comprehending the principal part of Franconia. It is bounded by the county of Henneburg, the duchy of Coburg, the abbey of Fuld, the archbishopric of Mentz, the marquisate of Anspach, the bishopric of Bamberg, and the county of Wertheim; being about 65 miles in length, and 50 in breadth, and divided into 50 bailiwicks. The soil is very fertile, and produces more corn and wine than the inhabitants consume. The territories of the bishop comprehend above 400 towns and villages, of which he is sovereign, being one of the greatest ecclesiastical princes of the empire.

WURZBURG, a large and handsome city of Germany, and one of the principal in the circle of Franconia. It is defended with good fortifications, and has a magnificent palace. There is a handsome hospital, in which are generally 400 poor men and women. The castle is at a small distance from the city, and commands it, as it stands upon an eminence. It communicates with the city by a stone-bridge, on which are 12 statues, representing as many saints. The arsenal and the cellars of the bishop deserve the attention of the curious. There is also an university, founded in 1403. It is seated on the river Maine, in E. Long. 10. 2. N. Lat. 49. 40.

WYCHERLEY (William), an eminent English comic poet, was born about 1640. A little before the restoration of King Charles II. he became a gentleman commoner of Queen's college Oxford, where he was reconciled by Dr Barlow to the Protestant religion, which he had a little before abandoned in his travels. He afterward entered himself in the Middle-temple, but soon quitted the study of the law for pursuits more agreeable to his own genius, as well as to the taste of the age. Upon writing his first play, intitled, *Love in a Wood*, or *St James's Park*, which was acted in 1672, he became acquainted with several of the celebrated wits both of the court and town, and likewise with the duchess of Cleveland. Some time after appeared his comedies, called *The Gentleman-Dancing-Master*, *The Plain Dealer*, and *The Country Wife*; all which were acted with applause. George duke of Buckingham had a very high esteem for him, and bestowed on him several advantageous posts. King Charles also showed him signal marks of favour; and once gave him a proof of his esteem, which perhaps never any sovereign prince before had given to a private gentleman. Mr Wycherley being ill of a fever, at his lodgings in Bow-street, the king did him the honour of a visit. Finding him extremely weakened, he commanded him to take a journey to the south of France, and assured him, at the same time, that he would order him 500 l. to defray the charges of the journey. Mr Wycherley accordingly went into France; and having spent the winter there, returned to England entirely restored to his former vigour. The king, shortly after his arrival, told him, that he had a son, who he was resolved should be educated like the son of a king, and that he could not choose a more proper man for his governor than Mr Wycherley; for which service 1500 l. *per annum* should be settled upon him.

Immediately after this offer he went down to Tunbridge, where walking one day upon the Well's-walk with his friend Mr Fairbeard of Gray's Inn, just as he came up to the bookseller's shop, the countess of Drogheda, a young widow, rich, noble, and beautiful, came there to enquire for *The Plain Dealer*; "Madam," says Mr Fairbeard, "since you are for the *Plain Dealer*, there he is for you;" pushing Mr Wycherley towards her. "Yes," says Mr Wycherley,

Wycherley, "this lady can bear plain-dealing: for she appears to be so accomplished, that what would be a compliment to others, would be plain-dealing to her." "No, truly, Sir," said the countess, "I am not without my faults, any more than the rest of my sex: and yet, notwithstanding, I love plain-dealing, and am never more fond of it than when it tells me of them." "Then, madam," says Mr Fairbeard, "you and the Plain-Dealer seem designed by Heaven for each other."—In short, Mr Wycherley walked a turn or two with the countess, waited upon her home, visited her daily while she staid at Tunbridge, and married her soon after without acquainting the king. By this step, which was looked upon as a contempt of his majesty's orders, he forfeited the royal favour. The countess of Drogheda settled her whole fortune upon him; but his title being disputed after her death, he was so reduced by the expences of the law and other incumbrances, as to be unable to satisfy the impatience of his creditors, who threw him into prison; and the bookseller who printed his Plain-Dealer, by which he got almost as much money as the other gained reputation, was so ungrateful as to refuse to lend him 20*l*. in his extreme necessity. In that confinement he languished seven years; but at length king James going to see the above play, was so charmed with it, that he gave immediate orders for the payment of his debts, and even granted him a pension of 200*l*. *per annum*. But that prince's bountiful intentions were in a great measure defeated merely through Mr Wycherley's modesty; he being ashamed to tell the earl of Mulgrave, whom the king had sent to demand it, a true state of his debts. He laboured under the weight of these difficulties till his father died, who left him 600*l*. a year. But this estate was under uneasy limitations, he being only a tenant for life, and not being allowed to raise any money for the payment of his debts. However, he took a method of doing it which few suspected to be his choice; and

this was making a jointure. He had often declared, that he was resolved to die married, though he could not bear the thoughts of living in that state again: accordingly, just at the eve of his death, he married a young gentlewoman with 1500*l*. fortune, part of which he applied to the uses he wanted it for. Eleven days after the celebration of these nuptials, in December 1715, he died, and was interred in the vault of Covent-garden church.

Besides his plays above-mentioned, he published a volume of poems in folio. In 1728 his posthumous works in prose and verse were published by Mr Theobald.

WYNDHAM (Sir William), descended of an ancient family, was born about the year 1687, and succeeded young to the title and estate of his father. On his return from his travels, he was chosen member for the county of Somerset; in which station he served in the three last parliaments of Queen Anne, and as long as he lived: after the change of the ministry in 1710, he was appointed secretary at war; and in 1713 was raised to be chancellor of the exchequer. Upon the breach between the earl of Oxford and lord Bolingbroke, he adhered to the interests of the latter. He was removed from his employment on the accession of George I. and falling under suspicion on the breaking out of the rebellion in 1715, was apprehended. He made his escape; a reward was published for apprehending him; he surrendered, was committed to the Tower, but never brought to a trial. After he regained his liberty, he continued in opposition to the several administrations under which he lived; and died in 1740.

WYKEHAM (William of). See WILLIAM.

WYE, a river of Wales, which rising on the confines of Cardiganshire, and running south-east, divides the counties of Radnor and Brecknock; then crossing Herefordshire, it runs south and falls into the mouth of the Severn at Chepstow.

X.

X or x, is the 20th letter of our alphabet, and a double consonant. It was not used by the Hebrews or ancient Greeks; for as it is a compound letter, the ancients, who used great simplicity in their writings, expressed this letter by its component letters *cs*. Neither have the Italians this letter, but express it by *ff*. X begins no word in our language but such as are of Greek original; and is in few others but what are of Latin derivation; as *perplex*, *reflexion*, *diffusion*, &c. We often express this found by single letters, as *cks*, in *backs*, *necks*; by *ks*, in *books*, *breaks*; by *cs*, in *access*, *accident*; by *ct*, in *action*, *union*, &c. The English and French pronounce it like *cs* or *ks*; the Spaniards like *c* before *a*, viz. *Alexandro*, as if it were *Aleccandro*. In numerals it expresseth 10, whence in old Roman manuscripts it is used for *denarius*; and as such seems to be made of two V's placed one over the other. When a dash is added over it, thus \bar{x} , it signifies 10,000.

XANTHIUM, in botany; a genus of plants of the class *monocia*, order *pentandria*, and arranged in the natural classification under the 49th order, *compositæ*. The male flowers are composite, common calyx imbricated; corollulæ monopetalous, tubular, quinquefid. Female: calyx involucreum of two leaves, containing two flowers; corolla 0; drupa,

dry, prickly; nucleus bilocular. There are five species, only one of which is a native of Britain, the *strumarium* or leis burdock. The stem of this plant is a foot and a half high, thick, often spotted; leaves heart-shaped, lobed, on long foot-stalks. Flowers, male and female, many together, in the axæ of the leaves. The leaves are bitter and astringent. A decoction of the whole plant affords a showy yellow colour, but it is better if only the flowers are used. Horses and goats eat it; cows, sheep, and swine refuse it.

XANTHOXYLUM. See ZANTHOXYLUM.

XEBEC, or ZEBEC, a small three-masted vessel, navigated in the Mediterranean Sea, and on the coasts of Spain, Portugal, and Barbary. See Plate CCCCLII, fig. 10.

The sails of the xebec are in general similar to those of the polacre, but the hull is extremely different from that and almost every other vessel. It is furnished with a strong prow: and the extremity of the stern, which is nothing more than a sort of railed platform or gallery, projects farther behind the counter and buttock than that of any European ship.

Being generally equipped as a corsair, the xebec is constructed with a narrow floor, to be more swift in pursuit of the enemy; and of a great breadth, to enable her to carry

Xanthoxyl-
tum,
Xebec.

Xenocrates. a great force of sail for this purpose without danger of overturning. As these vessels are usually very low built, their decks are formed with a great convexity from the middle of their breadth towards the sides, in order to carry off the water which falls aboard more readily by their scuppers. But as this extreme convexity would render it very difficult to walk thereon at sea, particularly when the vessel rocks by the agitation of the waves, there is a platform of grating extending along the deck from the sides of the vessel towards the middle, whereon the crew may walk dry-footed whilst the water is conveyed through the grating to the scuppers.

The xebecs, which are generally armed as vessels of war by the Algerines, mount from 16 to 24 cannon, and carry from 300 to 450 men, two-thirds of whom are generally soldiers.

By the very complicated and inconvenient method of working these vessels, what one of their captains of Algiers told Mr Falconer will be readily believed, viz. that every xebec requires at least the labour of three square-rigged ships, wherein the standing sails are calculated to answer every situation of the wind.

XENOCRATES, a celebrated ancient Grecian philosopher, was born at Chalcedon in the 95th Olympiad. At first he attached himself to Æschines, but afterwards became a disciple of Plato, who took much pains in cultivating his genius, which was naturally heavy. His temper was gloomy, his aspect severe, and his manners little tinctured with urbanity. These material defects his master took great pains to correct; frequently advising him to sacrifice to the Graces: and the pupil was patient of instruction, and knew how to value the kindness of his preceptor. As long as Plato lived, Xenocrates was one of his most esteemed disciples; after his death he closely adhered to his doctrine; and, in the second year of the 110th Olympiad, he took the chair in the academy, as the successor of Speusippus.

Xenocrates was celebrated among the Athenians, not only for his wisdom, but for his virtues. So eminent was his reputation for integrity, that when he was called upon to give evidence in a judicial transaction, in which an oath was usually required, the judges unanimously agreed, that his simple asseveration should be taken, as a public testimony to his merit. Even Philip of Macedon found it impossible to corrupt him. So abstemious was he with respect to food, that his provision was frequently spoiled before it was consumed. His chastity was invincible. Phryne, a celebrated Athenian courtesan, attempted without success to seduce him. Of his humanity the following pathetic incident is a sufficient proof: A sparrow, which was pursued by a hawk, flew into his bosom; he afforded it protection till its enemy was out of sight, and then let it go, saying, that he would never betray a suppliant. He was fond of retirement, and was seldom seen in the city. He was discreet in the use of his time, and carefully allotted a certain portion of each day to its proper business. One of these he employed in silent meditation. He was an admirer of the mathematical sciences; and was so fully convinced of their utility, that when a young man, who was unacquainted with geometry and astronomy, desired admission into the academy, he refused his request, saying, that he was not yet possessed of the handles of philosophy. In fine, Xenocrates was eminent both for the purity of his morals and for his acquaintance with science, and supported the credit of the Platonic school, by his lectures, his writings, and his conduct. He lived to the first year of the 116th Olympiad, or the 82 of his age, when he

lost his life by accidentally falling, in the dark, into a reservoir of water.

XENOPHANES, the founder of the Eleaic sect of philosophy among the Greeks, was born at Colophon probably about the 65th Olympiad. From some cause or other he left his country early, and took refuge in Sicily, where he supported himself by reciting, in the court of Hiero, elegiac and iambic verses, which he had written in reprehension of the theogonies of Hesiod and Homer. From Sicily he passed over into Magna Græcia, where he took up the profession of philosophy, and became a celebrated preceptor in the Pythagorean school. Indulging, however, a greater freedom of thought than was usual among the disciples of Pythagoras, he ventured to introduce new opinions of his own, and in many particulars to oppose the doctrines of Epimenides, Thales, and Pythagoras. Xenophanes possessed the Pythagorean chair of philosophy about seventy years, and lived to the extreme age of an hundred years, that is, according to Eusebius, till the 81st Olympiad. The doctrine of Xenophanes concerning nature is so imperfectly preserved, and obscurely expressed, that it is no wonder that it has been differently represented by different writers. Perhaps the truth is, that he held the universe to be one in nature and substance, but distinguished in his conception between the matter of which all things consist, and that latent divine force which, though not a distinct substance but an attribute, is necessarily inherent in the universe, and is the cause of all its perfection.

XENOPHON, an illustrious philosopher, general, and historian, was born at Athens in the 3d year of the 82d Olympiad. When he was a youth, Socrates, struck with his external appearance, determined to admit him into the number of his pupils. Meeting him by accident in a narrow passage, the philosopher put his staff across the path, and stopping him, asked, where those things were to be purchased which are necessary to human life? Xenophon appearing at a loss for a reply to this unexpected salutation, Socrates proceeded to ask him, where honest and good men were to be found? Xenophon still hesitating, Socrates said to him, "Follow me, and learn." From that time Xenophon became a disciple of Socrates, and made a rapid progress in that moral wisdom for which his master was so eminent. Xenophon accompanied Socrates in the Peloponnesian war, and fought courageously in defence of his country. He afterwards entered into the army of Cyrus as a private volunteer in his expedition against his brother. This enterprize proving unfortunate, Xenophon, after the death of Cyrus, advised his fellow soldiers to attempt a retreat into their own country. They listened to his advice; and having had many proofs of his wisdom as well as courage, they gave him the command of the army, in the room of Proxenus who had fallen in battle. In this command he acquired great glory by the prudence and firmness with which he conducted them back, through the midst of innumerable dangers, into their own country. The particulars of this memorable adventure are related by Xenophon himself in his Retreat of the Ten Thousand. After his return into Greece, he joined Agesilaus, king of Sparta, and fought with him against the Thebans in the celebrated battle of Chæronea. The Athenians, displeased at this alliance, brought a public accusation against him for his former conduct in engaging in the service of Cyrus, and condemned him to exile. The Spartans, upon this, took Xenophon, as an injured man, under their protection, and provided him a comfortable retreat at Scilluntæ in Elea. Here, with his wife and two children, he remained several years, and passed his time in the society of his friends, and

in writing those historical works which have rendered his name immortal. A war at length arose between the Spartans and Eleans; and Xenophon was obliged to retire to Lepreus, where his eldest son had settled. He afterwards removed, with his whole family, to Corinth, where, in the first year of the hundred and fifth Olympiad, he finished his days.

XENOPHON the Younger, a Greek writer, so called to distinguish him from the celebrated Xenophon, was born at Ephesus, and lived, according to some authors, before Heliodorus, that is, about the beginning of the 4th century. He is only known by his *Ephesiaca*, a Greek romance in five books, which is esteemed, and contains the amours or adventures of Abracomes and Anthia. This romance was printed at London, in Greek and Latin, in 1724, 4to.

XERXES I. the fifth king of Persia, memorable for the vast army he is said to have carried into the field against Leonidas king of Sparta; consisting, according to some historians, of 800,000 men, while others make it amount to 3,000,000, exclusive of attendants. The fleet that attended this prodigious land force is likewise made to consist of 2000 sail; and all the success they met with was the taking and burning the city of Athens; for the army was shamefully repulsed near the straits of Thermopylæ by Leonidas, and the fleet was dispersed and partly destroyed by Themistocles at the straits of Salamis, who had only 380 sail under his command. Xerxes was assassinated by Artabanus, chief captain of his guards, and his distinguished favourite. See SPARTA.

XIMENES (Francis), a justly celebrated cardinal, bishop of Toledo, and prime minister of Spain, was born at Torrelaguna, in Old Castile, in 1437, and studied at Alcala and Salamanca. He then went to Rome; and being robbed on the road, brought nothing back but a bull for obtaining the first vacant prebend: but the archbishop of Toledo refused it him, and threw him in prison. Being at length restored to liberty, he obtained a benefice in the diocese of Sigüenza, where cardinal Gonzales de Mendoza, who was the bishop, made him his grand vicar. Ximenes some time after entered among the Franciscans of Toledo; but being there troubled with visits, he retired to a solitude named *Castanet*, and applied himself to the study of divinity and the oriental tongues. At his return to Toledo, queen Isabella of Castile chose him for her confessor, and afterwards nominated him archbishop of Toledo; which, next to the papacy, is the richest dignity in the church of Rome. "This honour (says Dr Robertson) he declined with a firmness which nothing but the authoritative injunction of the pope was able to overcome. Nor did this height of promotion change his manners. Though obliged to display in public that magnificence which became his station, he himself retained his monastic severity. Under his pontifical robes he constantly wore the coarse frock of St Francis, the rents of which he used to patch with his own hands. He at no time used linen, but was commonly clad in hair-cloth. He slept always in his habit; most frequently on the floor or on boards, and rarely in a bed. He did not taste any of the delicacies which appeared at his table, but satisfied himself with that simple diet which the rule of his order prescribed. Notwithstanding these peculiarities, so opposite to the manners of the world, he possessed a thorough knowledge of its affairs, and discovered talents for business which rendered the fame of his wisdom equal to that of his sanctity." His first care was to provide for the necessities of the poor; to visit the churches and hospitals; to purge his diocese of usurers and places of debauchery; to degrade corrupt judges, and place in their room persons whom he knew to be distinguished by their probity and disinterested-

ness. He erected a famous university at Alcala; and in 1499 founded the college of St Ildephonsus. Three years after he undertook the Polyglot Bible; and for that purpose sent for many learned men to come to him at Toledo, purchased seven copies in Hebrew for 4000 crowns, and gave a great price for Latin and Greek manuscripts. At this Bible they laboured above 12 years. It contains the Hebrew text of the Bible; the version of the Septuagint, with a literal translation; that of St Jerom. and the Chaldee paraphrases of Oskelos; and Ximenes added to it a dictionary of the Hebrew and Chaldee words contained in the Bible. This work is called *Ximenes's Polyglot*. In 1517 pope Julius II. gave him the cardinal's hat, and king Ferdinand the Catholic entrusted him with the administration of affairs. Cardinal Ximenes was from this moment the soul of every thing that passed in Spain. He distinguished himself at the beginning of his ministry by discharging the people from the burdensome tax called *acavale*, which had been continued on account of the war against Granada; and laboured with such zeal and success in the conversion of the Mahometans, that he made 3000 converts, among whom was a prince of the blood of the kings of Granada. In 1509 cardinal Ximenes extended the dominions of Ferdinand, by taking the city of Oran in the kingdom of Algiers. He undertook this conquest at his own expence, and marched in person at the head of the Spanish army clothed in his pontifical ornaments, and accompanied by a great number of ecclesiastics and monks. Some time after, foreseeing an extraordinary scarcity, he erected public granaries at Toledo, Alcala, and Torrelaguna, and had them filled with corn at his own expence; which gained the people's hearts to such a degree, that to preserve the memory of this noble action they had an eulogium upon it cut on marble, in the hall of the senate-house at Toledo, and in the market-place. King Ferdinand dying in 1516, left cardinal Ximenes regent of his dominions; and the archduke Charles, who was afterwards the emperor Charles V. confirmed that nomination. The cardinal immediately made a reform of the officers of the supreme council and of the court, and put a stop to the oppression of the grandes. He vindicated the rights of the people against the nobility; and as by the feudal constitution the military power was lodged in the hands of the nobles, and men of inferior condition were called into the field only as their vassals, a king with scanty revenues depended on them in all his operations. From this state Ximenes resolved to deliver the crown; and issued a proclamation, commanding every city in Castile to enrol a certain number of its burghesses, and teach them military discipline; he himself engaging to provide officers to command them at the public expence. This was vigorously opposed by the nobles; but by his intrepidity and superior address he carried his point. He then endeavoured to diminish the possessions of the nobility, by reclaiming all the crown-lands, and putting a stop to the pensions granted by the late king Ferdinand. This addition made to the revenues enabled him to discharge all the debts of Ferdinand, and to establish magazines of warlike stores. The nobles, alarmed at these repeated attacks, uttered loud complaints; but before they proceeded to extremities, appointed some grandes of the first rank to examine the powers in consequence of which he exercised acts of such high authority. Ximenes received them with cold civility; produced the testament of Ferdinand, by which he was appointed regent, together with the ratification of that deed by Charles. To both these they objected; and he endeavoured to establish their validity. As the conversation grew warm, he led them insensibly to a balcony, from which they had a view of a large body of troops under arms, and of a formidable train of artillery.

Ximenes,
Xiphias.

"Behold (says he, pointing to these, and raising his voice) the powers which I have received from his Catholic majesty! With these I govern Castile; and with these I will govern it, till the king, your master and mine, takes possession of his kingdom!" A declaration so bold and haughtily silenced them, and astonished their associates. They saw that he was prepared for his defence, and laid aside all thoughts of a general confederacy against his administration. At length, from the repeated intreaties of Ximenes, and the impatient murmurs of the Spanish ministry, Charles V. embarked, and landed in Spain, accompanied by his favourites. Ximenes was advancing to the coast to meet him, but at Bos Equillos was seized with a violent disorder, which his followers considered as the effects of poison. This accident obliging Ximenes to stop, he wrote to the king, and with his usual boldness advised him to dismiss all the strangers in his train, whose number and credit already gave offence to the Spaniards, and earnestly desired to have an interview with him, that he might inform him of the state of the nation, and the temper of his subjects. To prevent this, not only the Flemings, but the Spanish grandees, employed all their address to keep Charles at a distance from Aranda, the place to which the cardinal had removed. His advice was now slighted and despised. Ximenes, conscious of his own integrity and merit, expected a more grateful return from a prince to whom he delivered a kingdom more flourishing than it had been in any former age, and a more extensive authority than the most illustrious of his ancestors had ever possessed; and lamented the fate of his country, about to be ruined by the rapaciousness and insolence of foreign favourites. While his mind was agitated by these passions, he received a letter from the king; in which, after a few cold and formal expressions of regard, he was allowed to retire to his diocese; and he expired a few hours after reading it in 1517, in the 81st year of his age.

This famous cardinal ought not to be confounded with

Roderic XIMENES, archbishop of Toledo, in the 13th century, who wrote a History of Spain in nine books; nor with several other Spanish writers of the name of Ximenes.

XIPHIAS, in zoology, the SWORD-FISH; a genus of fishes belonging to the order of *apodes*. The upper jaw terminates in a long sword-shaped rostrum, from which it is called the *sword-fish*: there are no teeth in the mouth; the gill-membrane has eight rays; and the body is somewhat cylindrical. There is but one species, *viz.* the *gladius*, found in the European ocean. This fish sometimes frequents our coasts, but is much more common in the Mediterranean Sea, especially in the part that separates Italy from Sicily, which has been long celebrated for it: the promontory Pelorus, now Capo di Faro, was a place noted for the resort of the xiphias, and possibly the station of the speculators, or the persons who watched and gave notice of the approach of the fish.

The ancient method of taking them is particularly described by Strabo, and agrees exactly with that practised by the moderns. A man ascends one of the cliffs that overhangs the sea: as soon as he spies the fish, he gives notice, either by his voice or by signs, of the course it takes. Another, that is stationed in a boat, climbs up the mast, and on seeing the sword-fish, directs the rowers towards it. As soon as he thinks they are got within reach, he descends, and taking a spear in his hand, strikes it into the fish; which, after wearying itself with its agitation, is seized and drawn into the boat. It is much esteemed by the Sicilians, who buy it up eagerly, and at its first coming into season give about sixpence English *per* pound. The season lasts from May till August. The ancients used to cut this fish into pieces and salt it; whence it was called *Tomus Thuri-*

anus, from Thuri, a town in the bay of Tarentum, where it was taken and cured.

The sword-fish is said to be very voracious, and that it is a great enemy to the tunny, who (according to Belon) are as much terrified at it as sheep are at the sight of a wolf. It is a great enemy to the waales, and frequently destroys them. See BALÆNA.

XYLO-ALOES, or ALOE-WOOD, in the materia medica, is the product of a tree growing in China and some of the Indian islands. See EXCÆCARIA.

This drug is distinguished into three sorts; the calambac or tambac, the common lignum aloes, and calambour.

The calambac, or finest aloes-wood, called by authors *lignum aloes præstantissimum*, and by the Chinese *subiang*, is the most refinous of all the woods we are acquainted with: it is of a light spongy texture, very porous, and its pores so filled up with a soft and fragrant resin, that the whole may be pressed and dented by the fingers like wax, or moulded about by chewing in the mouth, in the manner of mastich. This kind, laid on the fire, melts in great parts like resin, and burns away in a few moments with a bright flame and perfumed smell. Its scent, while in the mais, is very fragrant and agreeable; and its taste acrid and bitterish, but very aromatic and agreeable. It is so variable in its colour, that some have divided it into three kinds; the one variegated with black and purple; the second, with the same black, but with yellowish instead of purple; and the third, yellow alone like the yolk of an egg: this last is the least scented of the three. The variation, however, is owing to the trunk of the tree being itself of three different colours; and the heart of it is the valuable sort first described. The two following are supposed to be the other parts of the trunk; though this seems doubtful, especially in regard to the last sort, from the circumstance mentioned of its being found in large logs entire, and sometimes only the *heart*, which, as above noticed, constitutes the calambac.

The lignum aloes vulgare is the second in value. This is of a more dense and compact texture, and consequently less refinous than the other; there is some of it, however, that is spongy, and has the holes filled up with the right refinous matter; and all of it, when good, has veins of the same resin in it. We meet with it in small fragments, which have been cut and split from larger: these are of a tolerably dense texture in the more solid pieces, and of a dusky brown colour, variegated with refinous black veins. It is in this state very heavy, and less fragrant than in those pieces which show a multitude of little holes, filled up with the same blackish matter that forms the veins in others. The woody part of these last pieces is somewhat darker than the other, and is not unfrequently purplish, or even blackish. The smell of the common aloes-wood is very agreeable, but not so strongly perfumed as the former. Its taste is somewhat bitter and acrid, but very aromatic.

The calambour, called also *agaltochum sylvestre*, and *lignum aloes mexicanum*, is light and friable, of a dusky and often mottled colour, between a dusky green black and a deep brown. Its smell is fragrant and agreeable, but much less sweet than that of either of the others; and its taste bitterish, but not so much acrid or aromatic as either of the two former. This is said to be met with very frequently, and in large logs; and these sometimes entire, sometimes only the heart of the tree. This is the aloes-wood used by the cabinet-makers and inlayers.

This drug is esteemed a cordial taken inwardly; and is sometimes given in disorders of the stomach and bowels, and to destroy the worms. A very fragrant oil may be procured from it by distillation; which is recommended in paralytic cases from five to fifteen drops. It is at present,

however, but little used; and would scarce be met with any-where in the shops, but that it is an ingredient in some of the old compositions.

XYNOECIA, in Grecian antiquity, an anniversary feast observed by the Athenians in honour of Minerva, upon the sixteenth of Hecatombæon, to commemorate their leaving, by the persuasion of Theseus, their country-seats, in which they lay dispersed here and there in Attica, and uniting together in one body.

XYSTARCHA, in antiquity, the master or director of

the xylus. In the Greek gymnasium, the xylarcha was the second officer, and the gymnastarcha the first; the former was his lieutenant, and presided over the two xysti, and all exercises of the athletæ therein.

XYSTUS, among the Greeks, was a long portico, open or covered at the top, where the athletæ practised wrestling and running; the gladiators, who practised therein, were called *xystici*. Among the Romans, the xylus was only an alley, or double row of trees, meeting like an harbour, and forming a shade to walk under.

Y.

Y or *y*, the 23d letter of our alphabet: its sound is formed by expressing the breath with a sudden expansion of the lips from that configuration by which we express the vowel *u*. It is one of the ambigenial letters, being a consonant in the beginning of words, and placed before all vowels, as in *yard, yield, young, &c.* but before no consonant. At the end of words it is a vowel, and is substituted for the sound of *i*, as in *try, defry, &c.* In the middle of words it is not used so frequently as *i* is, unless in words derived from the Greek, as in *chyle, empyreal, &c.* though it is admitted into the middle of some pure English words, as in *dying, flying, &c.* The Romans had no capital of this letter, but used the small one in the middle and last syllables of words, as in *corymbus, onyx, martyr.* **Y** is also a numeral, signifying 150, or, according to Baronius 159; and with a dash atop, as \bar{Y} , it signified 150,000.

YACHT, or **YATCH**, a vessel of state, usually employed to convey princes, ambassadors, or other great personages, from one kingdom to another.

As the principal design of a yacht is to accommodate the passengers, it is usually fitted with a variety of convenient apartments, with suitable furniture, according to the quality or number of the persons contained therein.

The royal yachts are commonly rigged as ketches, except the principal one reserved for the sovereign, which is equipped with three masts like a ship. They are in general elegantly furnished, and richly ornamented with sculpture; and always commanded by captains in his majesty's navy.

Besides these, there are many other yachts of a smaller kind, employed by the commissioners of the excise, navy, and customs; or used as pleasure-boats by private gentlemen.

YAMS. See **DIOSCOREA.**

YAMBOO. See **EDGENIA.**

YARD of a **SHIP**, a long piece of timber suspended upon the masts of a ship, to extend the sails to the wind. See **MAST** and **SAIL.**

All yards are either square or lateen; the former of which are suspended across the masts at right angles, and the latter obliquely. See Plate **CCCCXLIV.** fig. 1.

The square yards are nearly of a cylindrical surface. They taper from the middle, which is called the *slings*, towards the extremities, which are termed the *yard-arms*; and the distance between the slings and the yard-arms on each side is by the artificers divided into quarters, which are distinguished into the first, second, third quarters, and yard-arms. The middle quarters are formed into eight squares, and each of the end parts is figured like the flu-

stum of a cone. All the yards of a ship are square except that of the mizen. Yard.

The proportions for the length of yards, according to the different classes of ships in the British navy, are as follows:

		Guns.
1000 : 'gun-deck :	{ 560 : }	{ 100
	{ 559 : }	{ 90 80
	{ 570 : }	{ 70
	{ 576 : }	{ 60
	{ 575 : }	{ 50
	{ 561 : }	{ 44
1000 : main-yard :	{ 880 : }	{ 100 90 80
	{ 874 : }	{ all the rest

To apply this rule to practice, suppose the gun-deck 144 feet. The proportion for this length is as 1000 is to 575, so is 144 to 83; which will be the length of the main-yard in feet, and so of all the rest.

		Guns.
1000 main-yard :	{ 820 : }	{ 100 90 80 60 44
	{ 847 : }	{ 70
	{ 840 : }	{ 24
1000 : main-yard :	{ 720 : }	{ 24
	{ 720 : }	{ all the rest
1000 : fore-yard :	{ 719 : }	{ 70,
	{ 726 : }	{ 24
	{ 715 : }	{ all the rest
1000 : main topfail-yard :	: main top gall. yard all the rates.	
1000 fore top fail-yard :	{ 696 : }	{ fore top gallon- 70
	{ 690 : }	{ yard. all the rest.
1000 : fore topfail yard :	{ 68 : }	{ 70
	{ 750 : }	{ all the rest.

Cross-jack and sprit-fail yards equal to the fore topfail-yard.

Sprit-topfail-yard equal to the fore top-gallant-yard.

The diameters of yards are in the following proportions to their length.

The main and fore yards five sevenths of an inch to one yard. The topfail, cross-jack, and sprit-fail yards, nine-fourteenths of an inch to one yard. The top gallant, mizen top-fail, and sprit-fail topfail yards, eight-thirteenthths of an inch to one yard.

The mizen yard five-ninths of an inch to one yard.

All studding-fail booms and yards half an inch to one yard in length.

The lifts of the main-yard are exhibited in the above figure by *gg*; the horses and their stirrups by *h, i*; the reef-tackles and their pendants by *k, l*; and the braces and brace-pendants by *m, n*.

The lateen-yards evidently derive their names from ha-

Yard
||
Yawning.

ving been peculiar to the ancient Romans. They are usually composed of several pieces fastened together by woodlings, which also serve as steps whereby the sailors climb to the peak or upper extremity, in order to furl or cast loose the sail.

The mizen-yard of a ship, and the main-yard of a bilander, are hung obliquely on the mast, almost in the same manner as the lateen-yard of a xebec, fettee, or polacre.

YARD, a measure of length used in Britain and Spain, consisting of three feet, chiefly to measure cloth, stuffs, &c.

YARD-ARM is that half of the yard that is on either side of the mast, when it lies athwart the ship.

YARDS also denotes places belonging to the navy, where the ships of war, &c. are laid up in harbour.—There are belonging to his majesty's navy six great yards, *viz.* Chatham, Deptford, Woolwich, Portsmouth, Sheerness, and Plymouth; these yards are fitted with several docks, wharfs, lanches, and graving places, for the building, repairing, and cleaning of his majesty's ships; and therein are lodged great quantities of timber, masts, planks, anchors, and other materials: there are also convenient store-houses in each yard, in which are laid up vast quantities of cables, rigging, sails, blocks, and all other sorts of stores needful for the royal navy.

YARE, among sailors, implies ready or quick: as, be yare at the helm; that is, be quick, ready, and expeditious at the helm. It is sometimes also used for bright by seamen: as, to keep his arms yare; that is, to keep them clean and bright.

YARE, a river of Norfolk, which runs from west to east through that county, passing by Norwich, and falling into the German sea at Yarmouth.

YARMOUTH, a sea-port town of Norfolk, with a market on Wednesdays and Saturdays, and a fair on Friday and Saturday in Easter-week for petty chapmen. It is seated on the river Yare, where it falls into the sea; and is a place of great strength, both by art and nature, being almost surrounded with water: and there is a draw-bridge over the river. It is esteemed the key of this coast, and is a clean handsome place, whose houses are well built, it being a considerable town for trade. It has one large church, and a neat chapel, and the steeple of St Nicholas's is so high that it serves for a sea mark. It is governed by a mayor. The harbour is a very fine one, though it is very dangerous for strangers in windy weather; and it has for its security a petty strong fort. It is 27 miles east of Norwich, and 112 north-east of London. E. Long. 1. 55. N. Lat. 52. 45.

YARMOUTH, a town of the Isle of Wight, in Hampshire, with a market on Fridays, and one fair on July 25th for toys. It is seated on the western part of the island, on the sea-shore, and is encompassed with water; for, not many years ago a channel was cut through the peninsula, over which there is a draw-bridge, and it is defended by a strong castle on the quay. It is a handsome place, whose houses are chiefly built with stone, and covered with slate; and it sends two members to parliament. The market is now disused. W. Long. 1. 28. N. Lat. 50. 40.

YARN, wool or flax spun into thread, of which they weave cloth. See CLOTH.

YARROW, in botany. See ACHILLEA.

YAWNING, an involuntary opening of the mouth, generally produced by weariness or an inclination to sleep. Yawning, according to Boerhaave, is performed by expanding at one and the same time all the muscles capable of spontaneous motion; by greatly extending the lungs; by drawing in gradually and slowly a large quantity of air; and gradually and slowly breathing it out, after it has been

restored for some time and rarified; and then restoring the muscles to their natural state. Hence the effect of yawning is to move, accelerate, and equally distribute all the humours through all the vessels of the body, and consequently to qualify the muscles and organs of sensation for their various functions.

Sanctorius observes, that a great deal is insensibly discharged, when nature endeavours to get rid of the retained perspirable matter, by yawning and stretching of the limbs. To these a person is most inclined just after sleep, because a greater quantity going off by the pores of the skin than at other times, whensoever a person wakes, the increasing contraction that then happens closes a great deal of the perspirable matter in the cutaneous passages, which will continually give such irritations as excite yawning and stretching; and such motions, by shaking the membranes of the whole body, and shifting the contacts of their fibres, and the inclosed matter, by degrees throw it off. Hence we see the reason why healthful strong people are most inclined to such motions, because they perspire most in time of sleep, and therefore have more of the perspirable matter to lodge in the pores, and greater irritations thereunto. The advantages of some little exercise just after waking in a morning are considerable, as it throws off all the perspirable matter that is ready for its exit out of the body. When yawning is troublesome, Hippocrates says that long deep respiration or drawing in the air at long intervals cures it.

YEAR, in astronomy and chronology. See ASTRONOMY, n^o 347. p. 520. and KALENDAR.

The ancient Roman year was the lunar year, which, as first settled by Romulus, consisted only of ten months; *viz.* 1. March, containing 31 days. 2. April, 30. 3. May, 31. 4. June, 30. 5. Quintilis, 31. 6. Sextilis, 30. 7. September, 30. 8. October, 31. 9. November, 30. 10. December, 30.—in all 304 days; which came short of the true lunar year by 50 days, and of the solar, by 61 days. Numa Pompilius corrected this irregular constitution of the year, and composed two new months, January and February, of the days that were used to be added to the former year.

The ancient Egyptian year, called also the *year of Nabonassar*, on account of the epocha of Nabonassar, is the solar year of 365 days, divided into 12 months, of 30 days each, besides five intercalary days added at the end. The names, &c. of the months are as follows: 1. Thoth. 2. Paophi. 3. Athyr. 4. Chojac. 5. Tybi. 6. Mecheir. 7. Phame-noth. 8. Pharmuthi. 9. Pachon. 10. Pauni. 11. Epi-phi. 12. Mefori; beside the *καιραι παχροναι*.

The ancient Greek year was lunar; consisting of 12 months, which at first had 30 days apiece, then alternately 30 and 29 days, computed from the first appearance of the new moon; with the addition of an embolismic month of 30 days every 3d, 5th, 8th, 11th, 14th, 16th, and 19th year of a cycle of 19 years; in order to keep the new and full moons to the same terms or seasons of the year. Their year commenced with that new moon, the full moon of which comes next after the summer solstice. The order, &c. of their months was thus: 1. Φανατορσιαν, containing 29 days. 2. Μπαχρητιαν' 30. 3. Βοηδρομιαν, 29. 4. Μαρμακτηριαν, 30. 5. Γοακφιαν, 29. 6. Ποσειδιαν, 30. 7. Ταρηνιαν, 29. 8. Ανθιστριαν, 30. 9. Ελαρβολιαν, 30. 10. Μαιχιαν, 30. 11. Θαργηλιαν, 29. 12. Σικεραριαν, 30.

The ancient Jewish year is a lunar year, consisting commonly of 11 months, which alternately contain 30 and 29 days. It was made to agree with the solar year, either by the adding of 11, and sometimes 12 days, at the end of the year, or by an embolismic month. The names and quanti-

ties of the months stand thus: 1. Nisan, or Abib, 30 days. 2. Ijar, or Zius, 29. 3. Sibon, or Siwan, 30. 4. Thammuz, or Tanmuz, 29. 5. Ab, 30. 6. Elul, 29. 7. Tifri, or Ethanim, 30. 8. Marchesvan, or Bul, 29. 9. Cisleu, 30. 10. Tebeth, 29. 11. Sabat, or Schebeth, 30. 12. Adar, in the embolismic year, 30. Adar, in the common year, was but 29. Note, in the defective year, Cisleu was only 29 days; and in the redundant year, Marchesvan was 30.

The Persian year is a solar year of about 365 days; consisting of 12 months of 30 days each, with 5 intercalary days added at the end.

The Arabic, Mahometan, and Turkish years, called also the year of the *Hegira*, is a lunar year, equal to 354 days, 8 hours and 48 minutes, and consists of 12 months, which contain alternately 30 and 29 days.

The Hindoo year differs from all these, and is indeed different in different provinces of India. The best account that we have of it is by Mr Cavendish, in the *Phil. Trans.* of the Royal Society of London for the year 1792. "Before I speak of the civil year of the Hindoos (says this eminent philosopher), it will be proper to say a few words of the astronomical year, by which it is regulated.

"The astronomical year begins at the instant when the sun comes to the first point of the Hindoo zodiac. In the year 1792, it began on April 9th, at 22h. 14' after midnight of their first meridian, which is about 41' of time west of Calcutta; but, according to Mr Gentil's account of the Indian astronomy, it began 3h. 24' earlier. As this year, however, is longer than ours, its commencement falls continually later, in respect of the Julian year, by 30' 26" in four years. This year is divided into 12 months, each of which corresponds to the time of the sun's stay in some sign; so that they are of different lengths, and seldom begin at the beginning of a day.

"The civil day in all parts of India begins at sunrise, and is divided into 60 parts called *dandas*, which are again divided into 60 *pasas*. In those parts of India in which the Benares almanac, or as it is there called *patras*, is used, the civil year is lunisolar, consisting of 12 lunar months, with an intercalary month inserted between them occasionally. It begins at the day after the new moon next before the beginning of the solar year. The lunar month is divided into 30 parts called *teethee*; these are not strictly of the same length, but are equal to the time in which the moon's true motion from the sun is 12°. From the new moon till the moon arrives at 12° distance from the sun is called the first *teethee*; from thence till it comes to 24°, is called the second *teethee*; and so on till the full moon, after which the *teethees* return in the same order as before.

"The civil day is constantly called by the number of that *teethee* which expires during the course of the day; and as the *teethee* is sometimes longer than one day, a day sometimes occurs in which no *teethee* ends. When this is the case, the day is called by the same number as the following day; so that two successive days go by the same name. It oftener happens, however, that two *teethees* end on the same day; in which case the number of the first of them gives name to the day, and there is no day called by the number of the last, so that a gap is made in the order of the days. In the latter part of the month the days are counted from the full moon, in the same manner as in the former part they are counted from the new moon; only the last day, or that on which the new moon happens, is called the *30th*, instead of the *15th*. It appears, therefore, that each half of the month constantly begins on the day after that on which the new or full moon falls; only sometimes the half month begins with the second day, the first being wanting.

"This manner of counting the days is sufficiently intricate; but that of counting the months is still more so.

"The civil year, as was before said, begins at the day after the new moon; and, moreover, in the years which have an intercalary month, this month begins at the day after the new moon; but notwithstanding this, the ordinary civil month begins at the day after the full moon. To make their method more intelligible, we will call the time from new moon to new moon the natural month. The civil month *Visākha*, the first in the Hindoo kalender, which extends from the 9th of our April to the 10th of May, begins at the day after that full moon which is nearest to the instant at which the sun enters *Mesha*, the first in order of the Indian signs, whether before or after; however, it is not always accurately the nearest.

"A consequence of this way of counting the months is, that the first half of *Chitra*, the last month in the Indian kalender, extending from March the 10th to April the 9th, falls in one year, and the latter half in the following year; and whenever the sun enters no sign during a natural month, this month is intercalary. The number of days in the month varies from 29 to 32. Indeed the Hindoo months, both solar and lunar, consist neither of a determinate number of days, nor are regulated by any cycle, but depend solely on the motions of the sun and moon; so that a Hindoo has no way of knowing what day of the month it is but by consulting his almanac; and what is more, the month ought sometimes to begin on different days, in different places, on account of the difference in latitude and longitude, not to mention the difference which may arise from errors in computation. This mode of computing time must be attended with many inconveniences; but in the transactions of civil life the Hindoos do not much regard it. A disagreement, however, in the computation of the *teethee*, which sometimes also happens, occasions no small perplexity; because by the *teethees* or lunar days are regulated most of their religious festivals. Every Brahmin in charge of a temple, or whose duty it is to announce the times for the observance of religious ceremonies, is therefore furnished with one of their almanacs; and if he be an astronomer, he makes such corrections in it as the difference of latitude and longitude render necessary."

New Year's Gift. See GIFT.

YEAST, or YEAST, a head or foam rising upon beer or ale while working or fermenting in the vat. See BREWING.

It is used for a leaven or ferment in the baking of bread, as serving to swell or puff it up very considerably in a little time, and to make it much lighter, softer, and more delicate. See BAKING, BARM, and BREAD.

Mr Henry has published a method of preparing *artificial yeast*, by which good bread may be made without the assistance of any other ferment. The method is this: Boil flour and water together to the consistence of treacle, and when the mixture is cold saturate it with fixed air. Pour the mixture thus saturated into one or more large bottles or narrow-mouthed jars; cover it over loosely with paper, and upon that lay a slate or board with a weight to keep it steady. Place the vessel in a situation where the thermometer will stand from 70° to 80°, and stir up the mixture two or three times in 24 hours. In about two days such a degree of fermentation will have taken place, as to give the mixture the appearance of yeast. With the yeast in this state, and before it has acquired a thoroughly vinous smell, mix the quantity of flour intended for bread, in the proportion of six pounds of flour to a quart of the yeast, and a sufficient portion of warm water. Knead them well together

Year,
Yeast.

Yeast
Yellow.

in a proper vessel, and covering it with a cloth, let the dough stand for 12 hours, or till it appears to be sufficiently fermented in the fore mentioned degree of warmth. It is then to be formed into loaves and baked. Mr Henry adds, that perhaps the yeast would be more perfect, if a decoction of malt were used instead of simple water.

It has lately been discovered, that a decoction of malt alone, without any addition, will produce a yeast proper enough for the purpose of brewing. This discovery was made by Joseph Senyor, servant of the reverend Mr Mason of Aston near Rotherham; and he received for it a reward of L. 20 from the Society for promoting Arts, Manufactures, and Commerce. The process is as follows: Procure three earthen or wooden vessels of different sizes and apertures, one capable of holding two quarts, the other three or four, and the third five or six: boil a quarter of a peck of malt for about eight or ten minutes in three pints of water; and when a quart is poured off from the grains, let it stand in the first or smaller vessel in a cool place till not quite cold, but retaining that degree of heat which the brewers usually find to be proper when they begin to work their liquor. Then remove the vessel into some warm situation near a fire, where the thermometer stands between 70 and 80 degrees Fahrenheit, and there let it remain till the fermentation begins, which will be plainly perceived within 30 hours: add then two quarts more of a like decoction of malt, when cool, as the first was; and mix the whole in the second or larger vessel, and stir it well in, which must be repeated in the usual way, as it rises in a common vat: then add a still greater quantity of the same decoction, to be worked in the largest vessel, which will produce yeast enough for a brewing of 40 gallons.

Common ale yeast may be kept fresh and fit for use several months by the following method: Put a quantity of it into a close canvas bag, and gently squeeze out the moisture in a screw-press till the remaining matter be as firm and stiff as clay. In this state it may be close packed up in a tight cask for securing it from the air; and will keep fresh, sound, and fit for use, for a long time. This is a secret that might be of great use to the brewers and distillers, who, though they employ very large quantities of yeast, seem to know no method of preserving it, or raising nurseries of it; for want of which they sustain a very considerable loss; whereas the brewers in Flanders make a very great advantage of supplying the malt distillers of Holland with yeast, which is rendered lasting and fit for carriage by this easy expedient.

YELL, one of the islands of Shetland, lying north-east from the main land, and divided from it by an arm of the sea, called *Yell-Sound*. By some it is thought to have been the *Thule* of the ancients. In the old descriptions it is said to be 20 miles long and 8 broad. It is very mountainous and full of moss; but there are pretty considerable pastures in which they feed a great many sheep; and it also affords plenty of peat. It has eight large harbours, which would not be thought despicable in other countries. Anciently it seems to have been pretty populous, since there are in it three churches, twenty chapels, and many brughs or Pictish forts.

YELLOW, one of the original colours of light.

YELLOW-Colour for House-painting. See **CHEMISTRY**, n^o 699

Naples YELLOW, a beautiful colour much used by painters, formerly thought to be prepared from arsenic, but now discovered to have lead for its basis.

YELLOW-Hammer, in ornithology. See **FRINGILLA**.

YELLOW-Fever. See **MEDICINE**, n^o 168.

YEMEN, a province of Arabia, stretching along the Red Sea and Indian Ocean, and forming a part of the county once known by the name of Arabia Felix.

YEOMAN, the first or highest degree among the plebeians of England, next in order to the gentry.

The yeomen are properly freeholders, who having land of their own, live on good husbandry.

YEOMEN is also a title of office in the king's household, of a middle place or rank between an usher and a groom.

YEOMAN of the Guard were anciently 250 men of the best rank under gentry, and of larger stature than ordinary, each being required to be six feet high. At present there are but 100 yeomen in constant duty, and 70 more not in duty; and as any of the 100 dies, his place is supplied out of the 70. They go dressed after the manner of King Hen. VIII.'s time. They formerly had diet as well as wages when in waiting; but this was taken off in the reign of Queen Anne.

YEST, or **YEAST**. See **YEAST**.

YEW, in botany. See **TAXUS**.

YNCA, an appellation anciently given to the kings of Peru, and the princes of their blood; the word literally signifying, lord, king, emperor, and royal blood.

YOKK, or **YOKE**, in agriculture, a frame of wood fitted over the necks of oxen, whereby they are coupled together, and harnessed to the plough.

YOKK of Land, in our ancient customs, was the space which a yoke of oxen, that is, two oxen, may plow in one day.

YOLK, the yellow part in the middle of an egg (see **EGG**). It contains a lymphatic substance mixed with a certain quantity of mild oil, which, on account of this mixture, is soluble in water. When exposed to heat, it assumes a consistence not so hard as the white of the egg; and when bruised gives out the oil which it contains. This oil has been used externally as a liniment.

YONNE, a river in France, which rising in Burgundy, and running north through Nivernois and Champaign, falls into the Seine at Montereau sur Yonne.

YORK, in Latin *Eboracum*, the capital of Yorkshire in England. This city is so ancient that the origin of it is uncertain. In the time of the Romans a legion was stationed here, it being then the capital of the Brigantes; and here died the emperor Severus, and Flavius Valerius Constantius Chlorus, father of Constantine the Great. There was then also a temple of Bellona here, and no less than three military ways went from hence. In the time of the Saxons it was erected into an archbishopric by Pope Honorius, to which are now subject the bishoprics of Chester, Durham, Carlisle, and the Isle of Man; though anciently 12 bishoprics in England, and all Scotland, were. A horn is still kept in the minister, by which Ulphius, one of the Saxon princes, bestowed all his lands and revenues upon the church.

This city suffered very much during the ravages of the Danes; but, after the conquest, it began to flourish again. The cathedral, which cost a long time and a great deal of money in building, is a most stately Gothic pile. Its chapter-house is particularly admired for its painted glass, its fine marble stalls, its pillars of alabaster, and curious contrivance. In it is the following line in gold letters:

Ut Rosa, flos florum, sic est Domus ista Donorum.

The choir is remarkable for its fine carvings, particularly the statues of all the English monarchs; and the windows are exquisitely painted with the history of the Bible. The lantern steeple is 70 feet square, and 188 high, and the windows are 45. At the south end is a circular light, called

ed the *marigold window* from the colour of its glass; and at the north end is a very large one, whose painting represents embroidery.

This city is generally reckoned the second city in England; but though it stands upon more ground, it is inferior in trade, wealth, and number of people, to Bristol. The inhabitants are reckoned at 12,784. It is situate in a fine plain, in the middle of the shire, on both sides the Ouse, walled and divided into four wards, containing 28 parishes. It enjoys large privileges and immunities, conferred upon it by a succession of kings from Henry II. and its chief magistrate has the title of *lord mayor*, which is an honour peculiar to it and London. Richard II. made it a county of itself. The conservancy of most of the rivers of the county, within certain limits, belongs to the lord mayor and aldermen. The middle arch of the bridge here over the Ouse is thought to equal the Rialto at Venice in architecture, height, and breadth, the diameter being 81 feet, and the height 51. Though this city is 60 miles distant from the sea, yet ships of 70 tons burden come up the river to it. The town-house or Guild-hall stands upon the bridge, and is superior in all respects to that of London. In the Popish times there were nine abbeys here, and a vast number of churches; but of the latter there are only 17 now. The steeple of that of Allhallows is reckoned the finest in England. The archbishop has a fine palace; and the assembly-room, designed by the earl of Burlington, is very noble. Here are plays, assemblies, concerts, and the like entertainments, at some house or other, almost every night in the week. In the old castle, built originally by William the Conqueror, and repaired in 1701, the assizes are kept. It serves also for the county-gaol, which is the neatest and pleasantest in England, with an area larger than that of the King's-bench, and it has a handsome chapel in it, with a good allowance for a preacher. This city has long given the title of *duke* to some branch of the royal family.

The plenty and cheapness of provisions induces many persons of small fortune, or that would live frugally, to take up their abode here; and the venerable remains of Roman antiquities, and those of a later date, as abbeys, churches, and castles, procure this city a visit from every curious traveller. Many Roman altars, urns, coins, inscriptions, &c. have been found; and Saxon coins are still extant that have been struck here. The members for this city have precedence of all others, except those of London, in the house of commons. An infirmary, after the manner of those of Bath, Bristol, &c. hath been erected in it; and a cotton manufacture established and brought to great perfection. Besides four weekly markets, it has a great many fairs; one, in particular, every other Thursday for cattle and sheep. W. Long. 1. 1. N. Lat. 53. 59.

YORKSHIRE, the largest county of England, bounded on the south by Derbyshire, Nottinghamshire, and Lincolnshire; on the north by Durham and Westmoreland; on the east by the German Ocean; and on the west by Lancashire and a part of Cheshire.—It is upwards of 80 miles in length from east to west, nearly as much in breadth, and about 360 in circumference, containing, in the whole, 26 hundreds or wapentakes, 49 market-towns, 563 parishes, 242 vicarages, with many chapels of ease, and 2330 villages. Its area is computed by some at 4684 square miles, by others at 3,770,000 acres, and its inhabitants at upwards of 300,000. It is divided into three parts or ridings, viz. the West, East, and North; so denominated from their situation, in respect of the city of York. Each of these is as large, if not larger, than any ordinary county. There are other divisions, as Richmondshire, Allertonshire, How-

denhire, Hallanshire, Craven, Cleveland, Marshland, Hol-New York, dernefs, &c.

As the soil and face of the country vary greatly, so does the air. In the hilly parts the air is good, but the soil very indifferent: of the lower some are marshy, others drier, and the soil of both rich; but the air of the former is more foggy and unhealthy than that of the latter. The manufactures of this country are cutlery and hard-wares; particularly knives, bits, and spurs; but the principal are stockings and woollen cloth, with which it supplies in a great measure Germany and the North. As to the produce, it abounds in corn, cattle, hortes, lead, and iron, coal, wood, lime, liquorice, alum, jet, &c. It lies wholly in the northern circuit, and much the greater part of it in the diocese of York; that only which is called *Richmondshire* belonging to the diocese of Chester. The members it sends to parliament are 30; of which two are for the shire and 28 for the towns.

New-York, one of the United States of America, is bounded towards the south-east by the Atlantic Ocean; east by Connecticut, Massachusetts, and Vermont; north by the 45th degree of latitude, which divides it from Canada; north-westwardly by the river Iroquois or St Lawrence, and the lakes Ontario and Erie; southwest and south by Pennsylvania and New Jersey. The whole state contains about 44,000 square miles, equal to 28,160,000 acres.

The settlements already made in this state are chiefly upon two narrow oblongs, extending from the city of New York east and north. The one east is Long Island, which is 140 miles long, and narrow, and surrounded by the sea. The one extending north is about 40 miles in breadth, and bisected by Hudson's river. And such is the interfection of the whole state by the branches of the Hudson, the Delaware, the Susquehannah, and other large rivers, that there are few places throughout its whole extent which are more than 15 or 20 miles from some navigable stream. There are few fish in the rivers, but in the brooks are plenty of trout; and on the lakes yellow perch, sun-fish, salmon-trout, cat-fish, and a variety of others.

The State, to speak generally, abounds with lakes, some of salt and others of fresh water. It is intersected by ridges of mountains running in a north-east and south west direction. Beyond the Alleghany mountains, however, the country is a dead level, of a fine rich soil, covered, in its natural state, with maple, beach, birch, cherry, black-walnut, locust, hickory, and some mulberry trees. On the banks of lake Erie are a few chestnut and oak ridges. Hemlock swamps are interspersed thinly through the country. All the creeks that empty into lake Erie have falls, which afford many excellent mill seats. East of the Alleghany mountains, the country is broken into hills with rich intervening valleys. The hills are clothed thick with timber, and when cleared afford fine pasture; the valleys, when cultivated, produce wheat, hemp, flax, pease, giats, oats, Indian corn. Of the commodities produced from culture, wheat is the staple; of which immense quantities are raised and exported. Indian corn and pease are likewise raised for exportation; and rye, oats, barley, &c. for home consumption. In some parts of the State excellent dairies are kept, which furnish for the market butter and cheese.

The situation of New York, with respect to foreign markets, has decidedly the preference to any other of the United States. It has at all seasons of the year a short and easy access to the ocean. Its exports to the West Indies are, biscuit, pease, Indian corn, apples, onions, boards, slaves, hortes, sheep, butter, cheese, pickled cyllers, beef, and pork. But wheat is the staple commodity of the State, of which

New York no less than 677,700 bushels were exported in the year 1775, besides 2555 tons of bread and 2828 tons of flour. Inspectors of flour are appointed to prevent impositions, and to see that none is exported but that which is deemed by them merchantable. Besides the above-mentioned articles, are exported flax-seed, cotton wool, sarsaparilla, coffee, indigo, rice, pig-iron, bar-iron, pot-ash, pearl-ash, furs, deer-skins, logwood, fustick, mahogany, bees wax, oil, Madeira wine, rum, tar, pitch, turpentine, whale fins, fish, sugars, molasses, salt, tobacco, lard, &c. but most of these articles are imported for re-exportation. In the year 1774, there were employed, in the trade of this State, 1075 vessels, whose tonnage amounted to 40,812.

Since the revolution the literature of the State has engaged the attention of the legislature. In one of their earliest sessions an act passed, constituting 21 gentlemen (of whom the governor and lieutenant-governor for the time being are members *ex officio*) a body corporate and politic, by the name and style of "The regents of the university of the State of New York." They are intrusted with the care of literature in general in the State, and have power to grant charters of incorporation for erecting colleges and academies throughout the state—are to visit these institutions as often as they shall think proper, and report their state to the legislature once a-year. All degrees above that of master of arts are to be conferred by the regents. A universal toleration is granted in religion.

The supreme legislative powers of the State are vested in two branches, a senate and assembly. The members of the senate are elected by the freeholders of the State, who possess freehold estates to the value of L. 100 clear of debts. For the purpose of electing senators, the State is divided into four great districts, each of which chooses a certain number.

The assembly of the State is composed of representatives from the several counties, chosen annually in May. Every male inhabitant of full age, who has resided in the State six months preceding the day of election, and possessing a freehold to the value of L. 20, in the county where he is to give his vote; or has rented a tenement therein of the yearly value of forty shillings, and has been rated and actually paid taxes—is intitled to vote for representatives in assembly. The number of representatives is limited to 300.

The supreme executive power of the State is vested in a governor chosen once in three years by the freemen of the State. The lieutenant governor is, by his office, president of the senate; and, upon an equal division of voices, has a casting vote; but has no voice on other occasions. The governor has not a seat in the legislature; but as a member of the council of revision and council of appointment, he has a vast influence in the State. The council of revision is composed of the chancellor, the judges of the supreme court, or any of them, and the governor. In the year 1790 the number of inhabitants in this State was 340,120, of whom 21,324 were negroes.

New-York, a city of North America, capital of the State of the same name. It is situated at the south-west point of an island, at the confluence of Hudson and East rivers, and is about four miles in circumference. The situation is both healthy and pleasant. Surrounded on all sides by water, it is refreshed by cool breezes in summer, and the air in winter is more temperate than in other places under the same parallel. York Island is 15 miles in length, and hardly one in breadth. It is joined to the main by a bridge called King's Bridge. The channels between Long and Staten Islands, and between Long and York Islands, are so narrow as, to occasion an unusual rapidity of the tides, which is in-

creased by the confluence of the waters of Hudson and East rivers. This rapidity, in general, prevents the obstruction of the channel by ice. There is no basin or bay for the reception of ships, but the road where they lie in East river is defended from the violence of the sea by the islands which interlock with each other; so that, except that of Rhode Island, the harbour of New York, which admits ships of any burden, is the best of the United States. The number of inhabitants in 1786 was 23,614. New York is 07 miles north-east of Philadelphia. W. Long. 74. 5. W. Lat. 40. 43.

YOUNG (Dr Edward), was the son of a clergyman of the same name, and was born about the year 1679. When sufficiently qualified, he was matriculated into All-Souls college, Oxford; and designing to follow the civil law, he took a degree in that profession. In this situation he wrote his poems called *The Last Day*, published in 1704; which coming from a layman gave universal satisfaction: this was soon after followed by another, intitled *The Force of Religion, or Vanquished Love*. These productions gained him a respectable acquaintance; he was intimate with Addison, and thus became one of the writers of the *Spectator*: but the turn of his mind leading him to the church, he took orders, was made one of the king's chaplains, and obtained the living of Welwyn in Hertfordshire, worth about L. 500 *per annum*, but he never rose to higher preferment. For some years before the death of the late prince of Wales, Dr Young attended his court pretty constantly; but upon his decease all his hopes of church preferment vanished; however, upon the death of Dr Hales, he was taken into the service of the princess-dowager of Wales, and succeeded him as her privy chaplain. When pretty far advanced in life, he married the lady Elizabeth Lee, daughter of the late earl of Litchfield. This lady was a widow, and had an amiable son and daughter, who both died young. What he felt for their loss, as well as for that of his wife, is finely expressed in his *Night Thoughts*, in which the young lady is characterised under the name of Narcissa; her brother by that of Philander; and his wife, though nameless, is frequently mentioned; and he thus, in an apostrophe to death, deploras the loss of all the three.

Insatiate archer, could not once suffice!

Thy shaft slew thrice, and thrice my peace was slain,
And thrice ere thrice yon moon renew'd her horn.

He wrote three tragedies, *The Revenge*, *Buffsris*, and *The Brothers*. His satires, called *Love of Fame the universal Passion*, are by many esteemed his principal performance; though Swift said the poet should have been either more angry or more merry; they have been characterised as a string of epigrams written on one subject, that tire the reader before he gets through them. His *Complaint*, or *Night Thoughts*, exhibit him as a moral and melancholy poet, and are esteemed his masterpiece. They form a species of poetry peculiarly his own, and in which he has been unrivalled by all those who attempted to write in this manner. They were written under the recent pressure of his sorrow for the loss of his wife, daughter, and son-in-law; they are addressed to Lorenzo, a man of pleasure and the world, and who, as it is insinuated by some, is his own son, but then labouring under his father's displeasure. As a prose-writer, he arraigned the prevailing manners of his time, in a work called *The Centaur not Fabulous*; and when he was above 80 years of age, published *Conjectures on Original Composition*. He published some other pieces; and the whole of his works are collected in 4 and 5 vols 12mo. Dr Young's turn of mind was naturally solemn; and he usually, when

when at home in the country, spent many hours of the day walking in his own church-yard among the tombs. His conversation, his writings, had all a reference to the life after this; and this turn of disposition mixed itself even with his improvements in gardening. He had, for instance, an alcove with a bench, so painted near his house, that at a distance it looked as a real one which the spectator was then approaching. Upon coming up near it, however, the deception was perceived, and this motto appeared, *Invisibilia non decipiunt*, "The things unseen do not deceive us." Yet, notwithstanding this gloominess of temper, he was fond of innocent sports and amusement; he instituted an assembly and a bowling-green in the parish of which he was rector, and often promoted the gaiety of the company in person. His wit was generally poignant, and ever levelled at those who testified any contempt for decency and religion. His epigram, spoken extempore upon Voltaire, is well known; who happening in his company to ridicule Milton, and the allegorical personages of Death and Sin, Young thus addressed him:

Thou art so witty, profligate, and thin,
You seem a Milton with his Death and Sin.

One Sunday preaching in office at St James's, he found, that though he strove to make his audience attentive he could not prevail. Upon which his pity for their folly got the better of all decorums, and he sat back in the pulpit and burst into a flood of tears. Towards the latter part of life he knew his own infirmities, and suffered himself to be in pupilage to his house-keeper; for he considered that, at a certain time of life, the second childhood of age demanded its wonted protection. His son, whose boyish follies were

long obnoxious to paternal severity, was at last forgiven in his will; and our poet died regretted by all, having performed all that man could do to fill his post with dignity. His death happened in 1765.

Youth
||
YU·X.

YOUTH, that state of man in which he approaches towards his greatest perfection of body.

YPRES, a handsome, large, and populous town of the Austrian Netherlands, with a bishop's see. It has a considerable manufactory in cloth and ferges, and every year in Lent there is a considerable fair. It is one of the barrier towns, but was besieged and taken by the French in 1744. It is seated on a fertile plain on the river Ypre, in E. Long. 2. 48. N. Lat. 50. 51.

YUCCA, ADAM'S NEEDLE, in botany; a genus of plants of the class *hexandria* and order *monogonia*. The corolla is campanulate and patent, there is no style, the capsule is trilobular. There are four species, none of which are natives of Britain. All of them are exceedingly curious in their growth, and are therefore much cultivated in gardens. The Indians make a kind of bread from the roots of this plant.

YULE, Yool, or *Iul*. See *IUL*.

YUNX, in zoology, a genus of birds of the order *picæ*. The bill is short, roundish, and pointed; the nostrils concave and naked; the tongue very long and cylindrical; there are two fore and two hind claws. There is only one species, the *torquilla*, wry-neck, which is a native of Europe, Asia, and Africa, and is often seen in Britain. It is ash-coloured above, with light black and brown strokes. Beneath light brown, with black spots. Tail ash-colour, with four black bars. Weight 1½ oz. Irides hazel. Length 7 inches. Migrates.

Z.

Z, or z, the 24th and last letter, and the 19th consonant of our alphabet; the sound of which is formed by a motion of the tongue from the palate downwards and upwards to it again, with a shutting and opening of the teeth at the same time. This letter has been reputed a double consonant, having the sound *ds*; but some think with very little reason: and, as if we thought otherwise, we often double it, as in *puzzle*, *muzzle*, &c. Among the ancients, Z was a numeral letter, signifying 2000; and with a dash added a-top, Z̄ signified 2000 times 2000, or 4,000,000.

In abbreviations this letter formerly stood as a mark for several sorts of weights; sometimes it signified an ounce and a half; and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram Troy weight; and it has in earlier times been used to express the third part of an ounce or eight scruples. ZZ were used by some of the ancient physicians to express myrrh, and at present they are often used to signify zinziber or ginger.

ZAARA, ZAPARA, SAHARA, or the *Desert*, a vast country of Africa, bounded on the north by Barbary, on the east by Fezzan and Casna, on the south by Tombuctoo, and on the west by the Atlantic Ocean. Zaara contains a variety of wandering nations, all proceeding from Arabs, Moors, and fugitive Portuguese, who took refuge there when the family of the Sherifs made themselves masters of the three kingdoms of Barbary. All these people bear indiscriminately the names of *Nars*, *Moors*, or *Arabs*. They

are subdivided into various nations, of which the most considerable are the Mongearts, Trasars, and Bracnars. The Mongearts lead a wandering life, and live chiefly on the milk of their flocks, with a little barley-meal, and some dates. The poorer sort go naked, except the females, who commonly wrap a clout about their middle, and wear a kind of bonnet on their head; but the wealthier sort have a kind of loose gown, made of blue calicoe, with large sleeves, that is brought them from Negro-land. When they move from one place to another for fresh pasture, water, or prey, most of them ride on camels, which have generally a sort of saddle between the bunch and the neck, with a string or strap run through their nostrils, which serves for a bridle; and instead of spurs they use a sharp bodkin. Their tents or huts are covered with a coarse stuff, made of camel's hair, and a kind of wool or moss that grows on the palm trees. These Arabs live here under the government of their sheiks or cheyks; as in Arabia, Egypt, and other places. The other two tribes are rather more civilized. They are all Mahometans.

Zaara,
Zabulon.

ZABULON (anc. geog.), one of the twelve tribes; bounded on the north by the tribes of Asher and Naphthali; on the east by the sea of Galilee; on the south by the tribe of Issachar or the brook Cison, which ran between both; on the west by the Mediterranean; so that it touched two seas, or was bimarous.

ZABULON (anc. geog.), a very strong town in the tribe

Zacynthus of that name, on the Mediterranean, firnamed *of men*, near
 ||
Zaleucus Ptolemais: its vicinity to which makes it probable that it
 was also Chabulon, unless either name is a faulty reading in
 Josephus; distant about 60 stadia from Ptolemais.

ZACYNTHUS (anc. geog.), an island to the south of
 Cephalenia 60 stadia, but nearer to Peloponnesus, in the I-
 onian Sea, formerly subject to Ulysses, in compass above
 160 stadia, woody and fruitful, with a considerable cogno-
 minal town and a port. The island lies over against Elis,
 having a colony of Achæans from Peloponnesus, over-against
 the Corinthian Gulf. Both island and town are now called
Zante.

ZAFFRE, is the oxyd of cobalt, employed for painting
 pottery ware and porcelain of a blue colour. The method
 of preparing it is as follows: The cobalt taken out of the
 mine is broken with hammers into pieces about the size of
 an hen's egg; and the stony involucre, with such other
 heterogeneous matters as are distinguishable by the eye, are
 separated as much as possible. The chosen mineral is then
 pounded in stamping mills, and sifted through brass wire
 sieves. The lighter parts are washed off by water, and it is
 afterwards put into a large flat-bottomed arched furnace, re-
 sembling a baking oven, where the flame of the wood rever-
 berates upon the ore; which is occasionally stirred and
 turned with long handled iron hooks or rakes; and the
 process is continued till it ceases to emit any fumes. The
 oven or furnace is terminated by a long horizontal gallery,
 which serves for a chimney; in which the arsenic, naturally
 mixed with the ore, sublimes. If the ore contains a little
 bismuth, as this semimetal is very fusible, it is collected at the
 bottom of the furnace. The cobalt remains in the state of a
 dark grey oxyd, and is called *zaffre*. One hundred pounds of
 the cobalt ore lose 20 and even 30 *per cent.* during this ope-
 ration, which is continued 4 or even 9 hours, according to
 the quality of the ore. The roasted ore being taken out
 from the furnace, such parts as are concreted into lumps
 are pounded and sifted afresh. Zaffre, in commerce, is
 never pure, being mixed with two or rather three parts of
 powdered flints. A proper quantity of the best sort of
 these, after being ignited in a furnace, are thrown into wa-
 ter to render them friable, and more easily reduced to pow-
 der; which, being sifted, is mixed with the zaffre, accord-
 ing to the before-mentioned dose; and the mixture is put
 into casks, after being moistened with water. This oxyd,
 fused with three parts of sand and one of pot-ash, forms a
 blue glass; which, when pounded, sifted, and afterwards
 ground in mills, included in large casks, forms *smalt*.

The blue of zaffre is the most solid and fixed of all the
 colours that can be employed in vitrification. It suffers no
 change from the most violent fire. It is successfully em-
 ployed to give shades of blue to enamels, and to the crystal-
 glasses made in imitation of some opaque and transparent
 precious stones, as the lapis lazuli, the turquois, the saphi-
 re, and others of this kind.

ZALEUCUS, a famous legislator of the Locrians, and
 the disciple of Pythagoras, flourished 500 years B. C. He
 made a law, by which he punished adulterers with the loss
 of both their eyes; and his son offending, was not absolved
 from this punishment: yet, to show the father as well as the
 just lawgiver, he put out his own right, and his son's left
 eye. This example of justice and severity made so strong
 an impression on the minds of his subjects, that no instance
 was found of the commission of that vice during the reign
 of that legislator. It is added, that Zaleucus forbade any
 wine being given to the sick on pain of death, unless it was
 prescribed by the physicians; and that he was so jealous of
 his laws, that he ordered, that whoever was desirous of
 changing them, should be obliged, when he made the pro-

posal, to have a cord about his neck, in order that he might
 be immediately strangled, if those alterations were esteemed
 no better than the laws already established. Diodorus Si-
 culus attributes the same thing to Charondas legislator of
 the Sybarites.

ZAMA (anc. geog.), a town of Chamane, a district of
 Cappadocia, of unknown situation.—Another Zama, of
 Mesopotamia, on the Saoras, to the south of Nisibis.—A
 third, of Numidia, distant five days journey to the west of
 Carthage: it was the other royal residence of the kings of
 Numidia, hence called *Zama Regia*. It stood in a plain;
 was stronger by art than nature; richly supplied with every
 necessary; and abounding in men, and every weapon both
 of defence and annoyance.

The last of these is remarkable for the decisive battle
 fought between the two greatest commanders in the world,
 Hannibal the Carthaginian and Scipio Africanus. Of this
 engagement, the most important perhaps that ever was fought,
 Mr Hooke gives us the following account.

“ Scipio drew up his army after the Roman manner, ex-
 cept that he placed the cohorts of the Principes directly be-
 hind those of the Hastati, so as to leave sufficient space for
 the enemy's elephants to pass through from front to rear.
 C. Lælius was posted on the left wing with the Italian horse,
 and Masinissa with his Numidians on the right. The in-
 tervals of the first line Scipio filled up with his Velites, or
 light-armed troops, ordering them, upon a signal given, to
 begin the battle; and in case they were repulsed, or broke
 by the elephants, to run back through the lanes before men-
 tioned, and continue on their flight till they were got be-
 hind the Triarii. Those that were wounded, or in danger
 of being overtaken, were to turn off to the right and left
 through the spaces between the lines, and that way escape
 to the rear.

“ The army thus drawn up, Scipio went from rank to
 rank, urging his soldiers to consider the consequences of a
 defeat and the rewards of victory: on the one hand, cer-
 tain death or slavery (for they had no town in Africa strong
 enough to protect them); on the other, not only a lasting
 superiority over Carthage, but the empire of the rest of the
 world.

“ Hannibal ranged all his elephants, to the number of
 above 80, in one front. Behind these he placed his merce-
 naries, consisting of 12,000 men, Ligurians, Gauls, Balears,
 and Mauritanians.

“ The new levies of Carthaginians and other Africans,
 together with 4000 Macedonians, under a general named
Sopater, composed the second line. And in the rear of all,
 at the distance of about a furlong, he posted his Italian
 troops, in whom he chiefly confided. The Carthaginian
 horse formed his right wing, the Numidians his left.

“ He ordered their several leaders to exhort their troops
 not to be discouraged by their own weakness, but to place
 the hope of victory in him and his Italian army; and parti-
 cularly directed the captains of the Carthaginians to repen-
 tent to them what would be the fate of their wives and chil-
 dren if the event of this battle should not prove successful.
 The general himself, walking through the ranks of his Ita-
 lian troops, called upon them to be mindful of the 17 cam-
 paigns in which they had been fellow-soldiers with him; and
 of that constant series of victories by which they had exting-
 uished in the Romans all hope of ever being conquerors.
 He urged them to remember, above all, the battles of Tre-
 bia, Thrasymenus, and Cannæ; with any of which the ap-
 proaching battle was in no wise to be compared, either
 with respect to the bravery or the number of the enemy.
 ‘ The Romans were yet unfoiled, and in the height of their
 strength, when you first met them in the field; nevertheless

you vanquished them. The soldiers now before us are either the children of the vanquished, or the remains of those whom you have often put to flight in Italy. Maintain therefore your general's glory and your own, and establish to yourselves the name of invincible, by which you are become famous throughout the world.

"When the Numidians of the two armies had skirmished a while, Hannibal ordered the managers of the elephants to drive them upon the enemy. Some of the beasts, frightened at the noise of the trumpets and other instruments of war which sounded on all sides, immediately ran back amongst the Numidians of the Carthaginian left wing, and put them into confusion; which Masinissa taking advantage of, entirely routed them. Great destruction was made of the Velites by the rest of the elephants, till these also being terrified, some of them ran through the void spaces of the Roman army which Scipio had left for that purpose; others falling in among the cavalry of the enemy's right wing, gave Lælius the same opportunity against the Carthaginian horse as had been given to Masinissa against the Numidian, and of which the Roman did not fail to make the same use. After this the infantry of the foremost lines joined battle. Hannibal's mercenaries had the advantage in the beginning of the conflict; but the Roman Hastati, followed and encouraged by the Principes, who exhorted them to fight manfully, and showed themselves ready to assist them, bravely sustained the attack, and at length gained ground upon the enemy. The mercenaries not being seasonably supported by their second line, and therefore thinking themselves betrayed, they in their retreat fell furiously upon the Africans; so that these, the Hastati coming up, were obliged to fight for some time both against their own mercenaries and the enemy. When the two Carthaginian lines had ceased their mutual rage, they joined their strength; and though now but a mere throng of men, broke the Hastati: but then the Principes advancing to the assistance of the latter, restored the battle; and most of the Africans and mercenaries were here cut off. Hannibal did not advance to their relief, the Roman Triarii not having yet engaged, and the Principes being still in good order; and left the routed Africans and mercenaries should break the ranks of his Italian soldiers, he commanded these to present their spears at those who fled to them for protection, which obliged the runaways to move off to the right and left.

"The ground over which the Romans must march before they could attack Hannibal being strewed with heaps of dead bodies and weapons, and being slippery with blood, Scipio feared that the order of his battalions would be broke, should he pass it hastily. To avoid this mischief, he commanded the Hastati to give over the pursuit, and halt where they were, opposite to the enemy's centre: after which, having sent all his wounded to the rear, he advanced leisurely with the Principes and Triarii, and placed them on the wings of the Hastati. Then followed a sharp engagement, in which victory was long and eagerly disputed. It would seem that the Romans, though superior in number, were once upon the point of losing the day; for Polybius tells us, that Masinissa and Lælius came very seasonably, and as if sent from heaven, to their assistance. These generals being returned from the pursuit of the cavalry, fell suddenly upon the rear of Hannibal's men, most of whom were cut off in their ranks; and of these that fled, very few escaped the horse, the country all around being a plain.

"There died of the Carthaginians in the fight above 20,000, and almost the like number were taken prisoners. The loss on the side of the Romans amounted to about 2000 men. Hannibal escaped with a few horse to Adu-

metum, having performed every thing in the engagement which could be expected from a great general. His army (says Polybius) could not have been more skilfully drawn up. For as the order of the Roman battalions makes it extremely difficult to break them, the Carthaginian wisely placed his elephants in the front, that they might put the enemy in confusion before the armies should engage. In his first line he placed the mercenaries; men bold and active, but not well disciplined, that by their impetuosity he might give a check to the ardour of the Romans. The Africans and Carthaginians, whose courage he doubted, he posted in the middle between the mercenaries and his Italian soldiers, that they might be forced to fight, or at least that the Romans, by slaughtering them, might fatigue themselves and blunt their weapons. Last of all, he drew up the troops he had disciplined himself, and in whom he chiefly confided, at a good distance from the second line, that the might not be broken by the route of the Africans and mercenaries, and kept them in reserve for a vigorous attack upon a tired and weakened enemy."

ZANGUEBAR, a country in Africa, lying on the eastern coast, between three degrees of north latitude, and 18 south. It includes several petty kingdoms, in which the Portuguese have various settlements. The inhabitants, except those converted by the Portuguese, are all Mahometans or idolaters; and the latter much the more numerous. The names of the principal territories are *Mombaza*, *Lamon*, *Melinda*, *Quiola*, and *Mosambique*. The Portuguese have built several forts in Mombaza and Mosambique, and have settled several colonies there. They trade with the negroes for slaves, ivory, gold, ostrich-feathers, wax, and drugs. The productions are much the same as in other parts of Africa between the tropics.

ZANONIA, in botany; the name of a genus of plants of the order *diazia*, class *pentandria*. The characters are these: it produces separate male and female flowers; in the male flower the cup is a perianthium, composed of three leaves of an oval figure, expanding every way, and shorter than the flower; the flower is monopetalous, but divided into five segments, and has an open mouth; the segments are jagged, and are equal in size, and bend backwards; the stamina are five filaments of the length of the cup, standing open at their ends, and terminated by simple apices; the female flowers grow on separate plants, and have the cup and flower the same as in the male, only that the cup stands upon the germen of the pistil; this germen is oblong, and from it are propagated three reflex conic styles; the stigmata are bifid and curled; the fruit is a long and very large berry, truncated at the end, and very small at the base; it contains three cells, and has a curled suture near the apex; the seeds are two; they are of an oblong figure, and flat. There is one species, the *india*.

ZANIE, an island of the Mediterranean, near the coast of the Morea, 19 miles south-east of the island of Cephalonia, belonging to the Venetians. It is about 24 miles in length and 12 in breadth, and very pleasant and fertile; but its principal riches consist in currants, with which it greatly abounds. They are cultivated in a very large plain, under the shelter of mountains on the shore of this island; for which reason the sun has greater power to bring them to perfect maturity. The town called *Zanie* may contain near 20,000 inhabitants; the whole island contains about 40,000. The houses are low, on account of the frequent earthquakes, for scarce a year passes without one; however, they do no great damage. The natives speak both Greek and Italian. There are very few Roman Catholics among them; but they have a bishop as well as the Greeks. This place has no fortifications, but there is a fortress upon an eminence planted

planted with cannon. In one part of this island is a place which shakes when trod upon like a quagmire; and a spring which throws out a great deal of bitumen, especially at the time of an earthquake. It serves instead of pitch to pay the bottoms of the ships, and about 100 barrels in a year are used for this purpose. There are about 50 villages in the island; but no other large town beside Zante. It is seated on the eastern side of the island, and has a good harbour. The English and Dutch have each a factory and consul here. E. Long. 21. 3. N. Lat. 37. 53.

ZANTHOXYLUM, the TOOTHACH-TREE, in botany; a genus of plants of the class of *diccia*, and order of *pentandria*; and in the natural system arranged under the 46th order, *Hederaceae*. The calyx is quinquepartite; there is no corolla; the female flower has five pistils and as many monospermous capsules. There are two species, the *clava herculis*, and the *trifoliatum*; neither of which are natives of Britain.

ZAPATA, a kind of feast or ceremony held in Italy, in the courts of certain princes, on St Nicholas's day; wherein people hide presents in the shoes or slippers of those they would do honour to, in such a manner as may surprize them on the morrow when they come to dress; being done in imitation of the practice of St Nicholas, who used in the night-time to throw purses of money in at the windows to marry poor maids withal.

ZEA, INDIAN CORN, in botany; a genus of plants of the class *monocia*, order *triandria*. The male-flowers are placed on distinct spikes; the calyx is a biflorous, beardless glume; the corolla a beardless glume; the female calyx is a bivalve glume, as is the corolla. There is one filiform, pendulous style; the seeds are solitary and buried in an oblong receptacle. There is only one species, the *Mays*, maize. The Indians in New England, and many other parts of America, had no other vegetable but maize or Indian corn for making their bread. They call it *wacchin*; and in the United States of America there is much of the bread of the country made of this grain, not of the European corn. In Italy and Germany also there is a species of maize which is the food of the poor inhabitants.

The ear of the maize yields a much greater quantity of grain than any of our corn ears. There are commonly about eight rows of grain in the ear, often more, if the ground be good. Each of these rows contains at least 30 grains, and each of these gives much more flour than a grain of any of our corn. The grains are usually either white or yellowish; but sometimes they are red, bluish, greenish, or olive-coloured, and sometimes striped and variegated. This sort of grain, though so essentially necessary to the natives of the place, is yet liable to many accidents. It does not ripen till the end of September; so that the rains often fall heavy upon it while on the stalk, and the birds in general peck it when it is soft and unripe. Nature has, to defend it from these accidents, covered it with a thick husk, which keeps off slight rains very well; but the birds, if not frightened away, often eat through it, and devour great quantity of the grain.

There are three or four varieties of maize in different parts of America. That of Virginia is very tall and robust, growing to seven or eight feet high; that of New England is shorter and lower. And the Indians farther up in the country have a yet smaller kind in common use. The stalk of the maize is joined like the sugar-cane; it is very soft and juicy, and the juice is so sweet and saccharine, that a syrup, as sweet as that of sugar, has been often made of it; and things sweetened with it have been found not distinguishable from those done with sugar. It has not been

tried yet whether it will crystallize into sugar; but in all probability it will.

The Americans plant this corn any time from the beginning of March to the beginning of June; but the best season is the middle of April. The savage Indians, who knew nothing of our account of months, used to guide themselves in the seed-time of this useful plant by the budding of some particular trees of that country, and by the coming up of a sort of fish into their rivers which they call the *aloose*. These things were both so regular, that they were in no danger of mistaking the time.

The manner of planting maize is in rows, at equal distances, every way about five or six feet. They open the earth with a hoe, taking away the surface to three or four inches deep, and of the breadth of the hoe; they then throw in a little of the finer earth, so as to leave the hoe four inches deep or thereabouts, and in each of these holes they place four or five grains at a little distance from one another. If two or three of these grow up, it is very well; some of them are usually destroyed either by the birds or other animals.

When the young plants appear, they hoe up the weeds from time to time; and when the stalk gathers some strength, they raise the earth a little about it, and continue this at every hoeing till it begins to put forth the ears; then they enlarge the hill of earth, round the root, to the size of a hop-hill, and after this they leave it till the time of harvest, without any farther care. When they gather the ears, they either immediately strip off the corn, or else hang up the ears, tied in traces at distances from one another; for if they are laid near together, they will heat and rot or else sprout and grow; but kept cool and separate, they will remain good all the winter. The best method is to thresh out the corn as soon as the harvest is over, to dry it well on mats in the sun, and then lay it up in holes of the ground, well lined with mats, grass, or the like, and afterwards covered at top with more earth. The most careful among the Indians use this method, and this sort of subterranean granary always proves good.

The uses of this plant among the Indians are very many. The great article is the making their bread of it; but besides this, the stalks, when cut up before they are too much dried, are an excellent winter food for cattle; but they usually leave them on the ground for the cattle to feed on. The husks about the ear are usually separated from the rest, and make a particular sort of fodder, not inferior to our hay. The Indian women have a way of sitting them into narrow parts, and they then weave them artificially into baskets and many other toys. The original way of eating the grain among the Indians was this: they boiled it whole in water till it swelled and became tender, and then they fed on it either alone or eat it with their fish and venison instead of bread. After this, they found the way of boiling it into a sort of pudding, after bruising it in a mortar; but the way of reducing it to flour is the best of all. They do this by parching it carefully in the fire, without burning, and then beating it in mortars and sifting it. This flour they lay up in bags as their constant provision, and take it out with them when they go to war, eating it either dry or with water. The English have contrived, by mixing it into a stiff paste, either by itself or with rye or wheat-meal, fermenting it with leaven or yeast, and baking it in a hot oven, to make good bread of it. They have likewise found out a method of making good beer, either of the bread or by making the grain.

ZEAL, passionate ardour for any person or cause. It is most frequently used to denote a strong and warm attachment

ment to the distinguishing doctrines or worship of some particular sect of Christians. Thus we say, a zealous *Calvinist*, *Arminian*, or *Papist*; though we may likewise with the greatest propriety say of an upright and benevolent man, that he is zealous of *good works*.

ZEALAND, the chief of the Danish islands, is situated at the entrance of the Baltic Sea, bounded by the Schagerrac Sea on the north; by the Sound, which separates it from Schonen, on the east; by the Baltic Sea on the south; and by the strait called the *Great Belt*, which separates it from the island of Funen, on the west; being of a round figure, near 200 miles in circumference: the chief town is Copenhagen.

ZEALAND, is also a province of the United Netherlands, consisting of eight islands, which lie in the mouth of the river Scheld, bounded by the province of Holland, from which they are separated by a narrow channel on the north; by Brabant on the east; by Flanders, from which they are separated by one of the branches of the Scheld, on the south; and by the German Ocean on the west.

New ZEALAND, a country of Asia, in the South Pacific Ocean, first discovered by Tasman, the Dutch navigator, in the year 1642, who gave it the name of *Staten Land*, though it has been generally distinguished in our maps and charts by the name of *New Zealand*, and was supposed to be part of a southern continent: but it is now known, from the late discoveries of Captain Cook who sailed round it, to consist of two large islands, divided from each other by a strait four or five leagues broad. They are situated between the latitudes of 34 and 48 degrees south, and between the longitudes of 166 and 180 degrees east from Greenwich. One of these islands is for the most part mountainous, rather barren, and but thinly inhabited; but the other is much more fertile, and of a better appearance. In the opinion of Sir Joseph Banks and Dr Solander, every kind of European fruits, grain, and plants, would flourish here in the utmost luxuriance. From the vegetables found here, it is supposed that the winters are milder than those in England, and the summers not hotter, though more equally warm; so that it is imagined, that if this country were settled by people from Europe, they would, with moderate industry, be soon supplied, not only with the necessaries, but the luxuries of life, in great abundance. Here are forests of vast extent, filled with very large timber trees; and near 400 plants were found here that had not been described by the naturalists. The inhabitants of New Zealand are stout and robust, and equal in stature to the largest Europeans. Their colour in general is brown, but in few deeper than that of the Spaniard who has been exposed to the sun, and in many not so deep; and both sexes have good features. Their dress is very uncouth, and they mark their bodies in a manner similar to the inhabitants of Otaheite, and which is called *tattooing*. Their principal weapons are lances, darts, and a kind of battle-axes; and they have generally shown themselves very hostile to the Europeans who have visited them.

ZEALOTS, an ancient sect of the Jews, so called from their pretended zeal for God's law and the honour of religion.

ZEBRA, in zoology. See *EQUUS*.

ZEBU, in zoology; a name given by M. de Buffon to the *bos indicus* of Linnæus. See *BOS*, vi.

ZECHARIAH, a canonical book of the Old Testament. See *SCRIPTURE*, ii. 80.

ZECHIN, or *ZECCHINO*. See *SEQUIN*.

ZEDOARY, in the materia medica. See *KÆMPFERIA*.

ZELL, a city of Germany in the circle of Lower Sa-

xony, capital of the duchies of Zell and Lunenburg, situated at the confluence of the rivers Aller and Fuhse, 30 miles north of Hanover, and 40 south of Lunenburg. E. Long. 10. 12. N. Lat. 52. 49.

ZEMBLA NOVA, a very large island, lying in the Northern Ocean, to the north of Russia, from which it is separated by the strait of Waigat. It has no inhabitants except wild beasts, particularly white foxes and bears. In 1595 a Dutch vessel was cast away on the coast, and the ship's company were obliged to winter here; but they did not see the sun from the fourth of November to the beginning of February, and had great difficulty to keep themselves from being frozen to death.

ZEMINDAR. See *HINDOSTAN*, Vol. VIII. page 585.

ZEND, or *ZENDAVESTA*, a book ascribed to Zoroaster, and containing his pretended revelations; which the ancient Magicians and modern Perfecs, called also *Gaurs*, observe and reverence in the same manner as the Christians do the Bible, and the Mahometans the Koran, making it the sole rule both of their faith and manners. The word, it is said, originally signifies any instrument for kindling fire, and is applied to this book to denote its aptitude for kindling the flame of religion in the hearts of those who read it.

The Zend contains a reformed system of Magianism; teaching that there is a Supreme Being, eternal, self-existent, and independent, who created both light and darkness, out of which he made all other things; that these are in a state of conflict, which will continue till the end of the world; that then there shall be a general resurrection and judgment; and that just retribution shall be rendered unto men according to their works; that the angel of darkness with his followers shall be confined to a place of everlasting darkness and punishment, and the angel of light with his disciples introduced into a state of everlasting light and happiness; after which light and darkness shall no more interfere with each other. The Zend also enjoins the constant maintenance of sacred fires and fire-temples for religious worship; the distinction of clean and unclean beasts; the payment of tithes to priests, which are to be of one family or tribe; a multitude of washings and purifications, resembling those of the Jewish law; and a variety of rules and exhortations for the exercise of benevolence and charity.

In this book there are many passages evidently taken out of the Scriptures of the Old Testament, particularly out of the Psalms of David: The author represents Adam and Eve as the first parents of all mankind, gives in substance the same account of the creation and deluge with Moses, differing indeed with regard to the former, by converting the six days of the Mosaic account into six times, comprehending in the whole 365 days; and speaks also of Abraham, Joseph, Moses, and Solomon. Moreover, Dr Baumgarten asserts, that this work contains doctrines, opinions, and facts, actually borrowed from the Jews, Christians, and Mahometans; whence, and from other circumstances, he concludes that both the history and writings of this prophet were probably invented in the later ages, when the fire-worshippers under the Mahometan government thought fit to vindicate their religion from the suspicion of idolatry.

At whatever period the Zend may have been written, we are assured by Dr Hyde that it is in the pure old Persian language, and in the character called *Peplavi*. Some parts of it contain the original text, and others Zoroaster's second thoughts subjoined, for explaining more fully his doctrine. These were occasioned by the opposition of ad-vertaries, and unforeseen circumstances which occurred during the fabrication of the imposture. About 300 years

Zend.

Zenith, Zeno. ago, when the old Persian language had become antiquated and little understood, one of the deſtours or high-prieſts among the Perſees compoſed the *Sadda*, which is a compendium in the vulgar or modern Perſic tongue, of thoſe parts of the Zend that relate to religion, or a kind of code of canons and precepts, drawn from the theological writings of Zoroaſter, ſerving as an authoritative rule of faith and practice for his followers. This *Sadda* is written in a low kind of Perſic verſe, and, as Dr Hyde informs us, it is *bonorum & malorum ſarrago*, having many good and pious things, and alſo very ſuperſtitious and trifling. See PERSEES and ZOROASTER.

ZENITH, in aſtronomy, the vertical point, or a point in the heavens directly over our heads.

ZENO ELEATES, an eminent Grecian philoſopher, was born at Elea about 504 years before Chriſt. He was a zealous friend of civil liberty, and is celebrated for his courageous and ſucceſsful oppoſition to tyrants; but the inconſiſtency of the ſtories related by different writers concerning him in a great meaſure deſtroys their credit. He choſe to reſide in his ſmall native city of Elea rather than at Athens, becauſe it afforded freer ſcope to his independent and generous ſpirit, which could not eaſily ſubmit to the reſtraints of authority. It is related, that he vindicated the warmth with which he reſented reproach, by ſaying, "If I were indifferent to cenſure, I ſhould alſo be indifferent to praiſe." The invention of the dialectic art has been improperly aſcribed to Zeno; but there can be no doubt that this philoſopher, and other metaphyſical diſputants in the Eleatic ſect, employed much ingenuity and ſubtlety in exhibiting examples of moſt of the logical arts, which were afterwards reduced to rule by Ariſtotle and others.

According to Ariſtotle, he taught, that nothing can be produced either from that which is ſimilar or diſſimilar; that there is only one being, God; who is eternal, homogeneous, and ſpherical, neither finite nor infinite, neither quieteſcent nor moveable; that there are many worlds; that there is in nature no vacuum; that all bodies are compoſed of four elements, heat and moiſture, cold and dryneſs; and that the body of man is from the earth, and his ſoul an equal mixture of theſe four elements. He argued with great ſubtlety againſt the poſſibility of motion. If Seneca's account of this philoſopher deſerves credit, he reached the higheſt point of ſcepticiſm, and denied the real exiſtence of external objects. The truth is, that after all that has been advanced by different writers, it is impoſſible to determine whether Zeno underſtood the term *One*, metaphyſically, logically, or phyſically; or whether he admitted or denied a nature properly divine.

ZENO, the founder of the ſect of the Stoics, was born about 300 years before Chriſt, at Citium in the iſland of Cyprus. This place having been originally peopled by a colony of Phœnicians, Zeno is ſometimes called a Phœnician. His father was by profeſſion a merchant, but diſcovering in the youth a ſtrong propenſity towards learning, he early devoted him to philoſophy. In his mercantile capacity he had frequent occaſion to viſit Athens, where he purchaſed for his ſon ſeveral of the writings of the moſt eminent Socratic philoſophers. Theſe he read with great avidity; and when he was about 30 years of age, he determined to take a voyage to a city which was ſo celebrated both as a mart of trade and of ſcience. If it be true, as ſome writers relate, that he brought with him a valuable cargo of Phœnician purple, which was loſt by ſhipwreck upon the coaſt of Piræus, this circumſtance will account for the facility with which he at firſt attached himſelf to a ſect whoſe leading principle was the contempt of riches. Upon his firſt arrival in Athens, going accidentally into the ſhop of a bookſeller, he

took up a volume of the Commentaries of Xenophon; and after reading a few paſſages, was ſo much delighted with the work, and formed ſo high an idea of the author, that he aſked the bookſeller where he might meet with ſuch men. Crates the Cynic philoſopher happening at that inſtant to be paſſing by, the bookſeller pointed to him, and ſaid, "Follow that man." Zeno attended upon the inſtructions of Crates, and was ſo well pleaſed with his doctrine that he became one of his diſciples. But though he admired the general principles of the Cynic ſchool, he could not eaſily reconcile himſelf to their peculiar manners. Beſides, his inquiſitive turn of mind would not allow him to adopt that indifference to every ſcientific enquiry which was one of the characteristic diſtinctions of the ſect. He therefore attended upon other maſters, who profeſſed to inſtruct their diſciples in the nature and cauſes of things. When Crates, diſpleaſed at his following other philoſophers, attempted to drag him by force out of the ſchool of Stilpo, Zeno ſaid to him, "You may ſeize my body, but Stilpo has laid hold of my mind." After continuing to attend upon the lectures of Stilpo ſeveral years, he paſſed over to other ſchools, particularly to thoſe of Xenocrates and Diodorus Cronus. By the latter he was inſtructed in dialeſtics. He was ſo much delighted with this branch of ſtudy, that he preſented to his maſter a large pecuniary gratuity, in return for his free communication of ſome of his ingenious ſubtleties. At laſt, after attending almoſt every other maſter, he offered himſelf as a diſciple of Polemo. This philoſopher appears to have been aware, that Zeno's intention in thus removing from one ſchool to another, was to collect materials from various quarters for a new ſyſtem of his own; for, when he came into Polemo's ſchool, he ſaid to him, "I am no ſtranger, Zeno, to your Phœnician arts; I perceive that your deſign is to creep ſlyly into my garden, and ſteal away my fruit." Polemo was not miſtaken in his opinion. Having made himſelf maſter of the tenets of others, Zeno determined to become the founder of a new ſect. The place which he made choice of for his ſchool was a public portico, adorned with the pictures of Polygnotus, and other eminent painters. It was the moſt famous portico in Athens, and called, by way of eminence, *Στοα*, "the Porch." It was from this circumſtance that the followers of Zeno were called *Stoics*.

In his perſon Zeno was tall and ſlender; his aſpect was ſevere, and his brow contracted. His conſtitution was feeble, but he preſerved his health by great abſtemiouſneſs. The ſupplies of his table conſiſted of figs, bread, and honey; notwithstanding which, he was frequently honoured with the company of great men. In public company, to avoid every appearance of an aſſuming temper, he commonly took the loweſt place. Indeed ſo great was his modeſty, that he ſeldom choſe to mingle with a crowd, or wiſhed for the company of more than two or three friends at once. He paid more attention to neatneſs and decorum in external appearance than the Cynic philoſophers. In his dreſs indeed he was plain, and in all his expences frugal; but this is not to be imputed to avarice, but a contempt of external magnificence. He ſhowed as much reſpect to the poor as to the rich; and converſed freely with perſons of the meaneſt occupations. He had only one ſervant, or, according to Seneca, none.

Zeno lived to the extreme age of 98; and at laſt, in conſequence of an accident, voluntarily put an end to his life. As he was walking out of his ſchool he fell down, and in the fall broke one of his fingers; upon which he was ſo affected with a conſciouſneſs of infirmity, that, ſtriking the earth, he ſaid, "Why am I thus impoſtured? I obey thy ſummons;" and immediately went home and ſtrangled himſelf.

self. He died in the first year of the 129th Olympiad. The Athenians, at the request of Antigonus, erected a monument to his memory in the Ceramicum.

We ought not to confound the two Zenos already mentioned with

ZENO, a celebrated Epicurean philosopher, born at Sidon, who had Cicero and Pomponius Atticus for his disciples, and who wrote a book against the mathematics, which, as well as that of Posidonius's refutation of it, is lost; nor with several other Zenos mentioned in history.

ZENOBIA, queen of Palmyra. See PALMYRA.

ZEOLITE. See CLAY, Vol. V. page 49. and MINERALOGY, Vol. XII. page 88.

ZEPHANIAH, a canonical book of the Old Testament. See SCRIPTURE, n^o 79.

ZEPHYR, the *West-Wind*, or that which blows from the cardinal point of the horizon opposite to the east.

ZEPHYRUS, one of the Pagan deities, was represented as the son of Aurora, and the lover of the nymph Chloris, according to the Greeks, or of Flora according to the Romans; and as presiding over the growth of fruits and flowers. He is described as giving a refreshing coolness to the air by his soft and agreeable breath, and as moderating the heat of summer by fanning the air with his silken wings. He is depicted under the form of a youth, with a very tender air, with wings resembling those of the butterfly, and with his head crowned with a variety of flowers. As the poets of Greece and Rome lived in a warm climate, they are lavish in their praise of this beneficent deity, and under his name describe the pleasure and advantage they received from the western breezes.

ZERDA. See CANIS, Sp. xiv.

ZERTA, the ZERTE, a fish caught in the rivers of Italy and some other places, of the figure of the eel, and called by authors *capito anadromus*, and the *blike*. It seldom grows to more than two pounds weight, and at times lives in rivers, at times in the sea; and is esteemed a very well tasted fish, especially a little before the season of its spawning. The zerte is that species of cyprinus described by Gesner and others under the name of *capito anadromus*.

ZEST, the woody thick skin quartering the kernel of a walnut; prescribed by some physicians, when dried and taken with white-wine, as a remedy against the gravel.

Zest is also used for a chip of orange or lemon peel; such as is usually squeezed into ale, wine, &c. to give it a flavour; or the fine oil which spurts out of that peel on squeezing it.

ZEUGMA, a figure in grammar, whereby an adjective or verb which agrees with a nearer word, is also, by way of supplement, referred to another more remote.

ZEUS, in ichthyology, a genus of fishes of the order of *thoracici*. The head is compressed, and declines, the upper lip being vaulted over by a transverse membrane; the tongue is subulated; there are seven rays in the gill membrane; and the body is compressed.—The species are eight; of which the most remarkable is the *saber* or *dorce*. It is of a hideous form, its body is oval, and greatly compressed on the sides; the head large; the snout vastly projecting; the mouth very wide; the teeth very small; the eyes great, the irides yellow; the lateral line oddly distorted, sinking at each end, and rising near the back in the middle; beneath it on each side is a round black spot. The tail is round at the end, and consists of 15 yellow rays. The colour of the sides is olive, varied with light blue and white, and while living is very resplendent, and as if gilt; for which reason it is called the *dorce*. The largest fish we have heard of weighed 12 pounds.

Superstition hath made the *dorce* rival to the haddock,

for the honour of having been the fish out of whose mouth St Peter took the tribute-money, leaving on its sides those incontestible proofs of the identity of the fish, the marks of his finger and thumb. It is rather difficult at this time to determine on which part to decide the dispute; for the *dorce* likewise asserts an origin of its spots of a similar nature, but of a later date than the former. St Chrysostom, in wading through an arm of the sea, having caught a fish of this kind *en passant*, as an eternal memorial of the fact, left the impressions on its sides to be transmitted to all posterity. In our own country it was very long before this fish attracted our notice, at least as an edible one. We are indebted to the late Mr Quin for adding a most delicious fish to our table, who, overcoming all the vulgar prejudices on account of its deformity, has effectually established its reputation. This fish was supposed to be found only in the southern seas of this kingdom, but it has been discovered likewise on the coast of Anglesey. Those of the greatest size are taken in the Bay of Biscay, off the French coasts; they are also very common in the Mediterranean: Ovid must therefore have styled it *rarus saper*, on account of its excellency, not its scarcity.

ZEUXIS, a celebrated painter of antiquity, flourished about 400 years before Christ. He was born at Heraclea; but as there have been many cities of that name, it cannot be certainly determined which of them had the honour of his birth. Some learned men, however, conjecture, that it was the Heraclea near Crotona in Italy. He carried painting to a much higher degree of perfection than Apollodorus had left it; discovered the art of properly disposing of lights and shades, and particularly excelled in colouring. He amassed immense riches; and then resolved to sell no more of his pictures, but gave them away; saying very frankly, "That he could not set a price on them equal to their value." Before this time he made people pay for seeing them; and nobody was admitted to see his *Heleia* without ready money, which occasioned the wags calling his picture *Heleia the Courtesan*. It is not known whether this Helen of Zeuxis was the same with that which was at Rome in Pliny's time, or that which he painted for the inhabitants of Crotona to be hung up in the temple of Juno: this last he painted from five beautiful girls of that city, copying from each her greatest excellencies. Pliny observes, that this admirable painter, disputing for the prize of painting with Parrhasius, painted some grapes so naturally, that the birds flew down to peck them. Parrhasius, on the other hand, painted a curtain so very artfully, that Zeuxis mistaking it for a real one that hid his rival's work, ordered the curtain to be drawn aside, to show what Parrhasius had done; but having found his mistake, he ingenuously confessed himself vanquished, since he had only imposed upon birds, while Parrhasius had deceived even a master of the art. Another time he painted a boy loaded with grapes; when the birds also flew to this picture, at which he was vexed; and confessed, that this work was not sufficiently finished, since had he painted the boy as perfectly as the grapes, the birds would have been afraid of him. Arche-laus, king of Macedon, made use of Zeuxis's pencil for the embellishment of his palace. One of this painter's finest pieces was a Hercules strangling some serpents in his cradle, in the presence of his affrighted mother: but he himself chiefly esteemed his *Athleta*, or *Champion*, under which he placed a Greek verse that afterwards became very famous, and in which he says, "That it was easier to criticize than to imitate the picture." He made a present of his *Alcmena* to the Agrigentines. Zeuxis did not value himself on speedily finishing his pictures; but knowing that Agatharchus gloried in his being able to paint with ease and in a

Ziclag
||
Zinc.

little time, he said, "That for his part he, on the contrary, gloried in his slowness; and if he was long in painting, it was because he painted for eternity." Verrius Flaccus says, that Zeuxis having painted an old woman, he laughed so very heartily at the sight of this picture, that he died: but as no other of the ancients have mentioned this particular, there is the greatest reason to believe it fabulous. Carlo Dati has composed in Italian the Life of Zeuxis, with those of Parrhasius, Apelles, and Protogenes. This work was printed at Florence in 1667.

ZICLAG, or ZIKLAG (anc. geog.), a town of the tribe of Simeon, on the borders of the Philistines (Joshua xv. and xix.), but in the hands of the Philistines till David's time (1 Sam. xxvii. and xxx.)

ZIMB, in natural history. See ETHIOPIA, n° II.

ZIMEN T-WATER, COPPER-WATER, in natural history, the name by which some have called water found in places where there are copper-mines, and lightly impregnated with particles of that metal.

The most famous spring of this kind is about a mile distant from Newfol in Hungary, in the great copper-mine called by the Germans *herrn grundt*. The water in this mine is found at different depths, and is received into basins, for the purpose of separating the copper from it: in some of these it is much more sated with this metal than in others, and will make the supposed change of iron into that metal much sooner. The most common pieces of iron used in the experiments are horse-shoes, nails, and the like; and they are found very little altered in shape, after the operation, except that their surfaces are more raised. The water appears greenish in the basin, where it stands; but if a glass of it be taken up, it looks clear as crystal: it has no smell, but a strong vitriolic astringent taste, insomuch that the lips and tongue are blistered and scorched upon tasting it.

ZIN (anc. geog.), a wilderness encompassing Idumea, at least on the south and west, as far as Palestine or Canaan; but according to Wells, on the east of Edom, to the north of Ezion-gaber.

ZINC, a semimetal. For a description of the ores of this metal, the method of extracting it from these ores, and for its properties, see CALAMINE; CHEMISTRY-index; MINERALOGY, Vol. XII. page 128; METALLURGY, Part II. sect. xii.

Zinc, besides its medical qualities (for which see PHARMACY-index), is of great use in the arts: united with copper in different proportions, it forms brass and pinchbeck; and united with tin, it forms a kind of pewter.

Brass is formed by mixing two parts of copper with one of zinc; pinchbeck by mixing three or four parts of copper to one of zinc: when the metals are mixed in equal quantities they form a very exact imitation of gold. Its inflammable property renders zinc a useful ingredient in fire-works.

It has been proposed to substitute this semimetal instead of tin in the lining of copper vessels; the latter being thought insufficient to prevent the dangerous effects of the copper. Mr Malouin, who has made many experiments on the lining of vessels in this manner, asserts that it spreads more evenly on the copper than tin itself; that it is much harder and less fusible, and consequently more durable than tin. Mr Macquer owns these advantages; but thinks it dangerous to be used in culinary vessels, as it is soluble in vegetable acids, and the combination of it with the vitriolic acid is known to be a strong emetic. Gaubius also mentions a celebrated remedy for convulsive disorders, named *luna fixta ludemaunic* which Macquer affirms to be strongly emetic in very small doses. "But, may it not be presumed (says Foucroy), that properties which are applicable only to the vitriol and

flower zinc, cannot be applied to the semimetal itself, nor even, without farther experiments, to the salts formed by its combination with the vegetable acids." Mr de la Plandie, doctor in medicine of the faculty of Paris, has changed this presumption into certainty by experiments made with great care on himself. He took the salts of zinc, formed by its combination with vegetable acids, in a much stronger dose than the aliments prepared in copper covered with zinc can possibly contain them, and found no dangerous effects to follow. However, since objects which relate to the health and lives of mankind cannot be treated with too much circumspection, it appears to be prudent, and even necessary, not to decide on the subject till after a great number of experiments, and that the action of zinc combined with the vegetable acids used in cookery have been fully ascertained. The flowers of zinc have been used as an antispasmodic, and are an article of our present materia medica; but it does not clearly appear what success may be expected from them.

ZINNIA, in botany; a genus of plants of the class *syngenesia*, order *polygamia superflua*; and in the natural system arranged under the 49th order, *Composita*. The receptacle is paleaceous, the pappus consists of two erect awns, the calyx is ovato-cylindrical and imbricated; the rays consist of five persisting entire florets. There are two species, the *pauciflora* and *multiflora*, neither of which is a native of Britain.

ZINZENDORFF (Nicholas Lewis), count, was the noted founder of the German religious sect called *Moravians*, or *Herrnhuters*, or, as they pretend, the restorer of that society. From his own narrative it appears, that when he came of age in 1721, his thoughts were wholly bent on gathering together a little society of believers, among whom he might live, and who should entirely employ themselves in exercises of devotion under him. He accordingly purchased an estate at Bertholdsdorf in Upper Lusatia, where being joined by some followers, he gave the curacy of the village to a man of his own complexion; and Bertholdsdorf soon became talked of for a new mode of piety. One Christian David, a carpenter, brought a few proselytes from Moravia: they began a new town about half a league from the village, where count Zirzendorff fixed his residence among them, and where great numbers of Moravians flocked and established themselves under his protection: so that in 1732 their number amounted to 600. An adjacent hill, called the *Huibberg*, gave occasion to these colonists to call their new settlement *Huth des Herrn*, and afterward *Herrnhuth*; which may be interpreted "The guard or protection of the Lord:" and from this the whole sect have taken their name. The count spared neither pains nor art to propagate his opinions; he went himself all over Europe, and at least twice to America; and sent his missionaries throughout the world. Count Zinzendorff died in 1760. Those who wish to know more of the Moravian tenets may consult Rimius's account of them, translated in 1753. See UNITED BRETHREN.

ZISCA (John), a famous general of the forces of the Hussites, in the 15th century, was a gentleman educated at the court of Bohemia, in the reign of Wenceslaus. He entered very young into the army, and after distinguishing himself on several occasions, lost an eye in a battle, whence he was called *Zisca* or *One-eyed*. At length the Reformation, begun by John Huss, spreading through almost all Bohemia, Zisca placed himself at the head of the Hussites, and had soon under his command a body of 40,000 men. With this army he gained several victories over those of the Romish religion, who carried on a kind of crusade against them, and built a town in an advantageous situation, to which he gave the name of *Tabor*; whence the Hussites were

er were afterwards called *Taborites*. Zisca lost his other eye by an arrow at the siege of the city of Rubi; but this did not prevent his continuing the war, his fighting battles, and gaining several great victories, among which was that of Aunig on the Elbe, in which 9000 of the enemy were left dead on the field. The emperor Sigismund, alarmed at his progress, caused very advantageous proposals to be offered to him; which he readily accepted, and set out to meet Sigismund, but died on the road. He ordered that his body should be left a prey to the birds and wild beasts; and that a drum should be made of his skin, being persuaded that the enemy would fly as soon as they heard the sound. It is added, that the Hussites executed his will; and that the news of this order made such an impression on the disturbed imaginations of the German Papists, that in many battles they actually fled at the beat of the drum with the utmost precipitation, leaving their baggage and artillery behind them.

ZINZIBER, or ZINGIBER, in botany. See AMOMUM and GINGER.

ZION, or SION (anc. geog.), a very famous mountain, standing on the north side of the city of Jerusalem, (Psal. xlvii. 2.); containing the upper city, built by King David; and where stood the royal palace, (Josephus). A part of Zion, situated at its extremity, was called *Millo*, of, or in the city of David, (2 Chron. xxxii. 5.) Modern travellers, who have been upon the spot, say, that Zion is the whole of the mountain, on which Jerusalem stands at this day, though not to the extent in which it anciently stood on the same mountain, as appears Psal. ix. 12. 15. lxxv. 1. lxxxvii. 2, 3. Is. lxiii. 1. It is swelled into several eminences or tops; as Moriah, Acra Bezetha, and Zion a particular eminence of mount and Zion Proper, &c. encompassed on three sides, east, west, and south, with one continued very deep and steep valley; by means of which it was impregnable on these three sides, and always attacked and taken, according to Josephus, by the enemy on the north side, where mount Zion becomes level, and the vales of Gihon and Jehosaphat gradually lose themselves. This deep and steep valley incontestibly constitutes the compass of the old Jerusalem on those three sides, as plainly appears to any person who has been upon the spot. On that particular top of the mount called *Zion* stood the fortress of the Jebusites; which being afterwards taken by David, came to be called the *City of David*, where he had his royal residence and kept his court. That part of the valley which lay to the east was called *Jehosaphat's*, having mount Olivet lying beyond it; that to the south, *Gehinnon*; and that to the west, *Gihon*, from cognominal mountains lying beyond them. At the west end of Gihon, without the city, stood Golgotha or Calvary. The pretended Golgotha, shown at this day within the walls, is the spurious brat of interested and fraudulent monks, (Korte). There is another *Zion*, the same with *HERMON*.

ZION, or *Sion College*. See LONDON, n° 76.

ZIPH, or SIPH (anc. geog.), the name of a wilderness or desert in the tribe of Judah, where David was a fugitive; lying to the south-east of Hebron; so called from Ziph or Siph, a twofold town in this tribe; the one more to the south towards Idumea, on the confines of Eleutheropolis, (Jerome); the other eight miles to the east of Hebron, towards the Dead Sea, inclining southwards, because near mount Carmel. Here was a mountain, mentioned 1 Sam. xxiii. 14. in which David abode, said by Jerome to be rugged, dismal, and always overcast. *Ziphim*, *Ziphzi*, or *Ziphnes*, the inhabitants of Ziph, ver. 19.

ZIRCHNITZER-SEE, otherwise called the *Lake of Czirknitz*, in Carniola, is about one German or four English miles in length, and half as much in breadth, contains three beautiful islands, and is encompassed at some distance with

mountains and forests. But what is most remarkable is, that it disappears generally once a-year, about St John's or St James's day, running off through holes or pits in the bottom; sometimes it will disappear twice or thrice a-year, and sometimes even in winter if the weather be dry. On the other hand, it has been known to continue two or three years without running off. Of the holes or pits, there are five much larger than the rest, each of which successively, when the water runs off, stands empty five days; so that the whole lake becomes dry in 25. As soon as the beginning of the ebb is observed, the fishing in the pits begins, which belongs to five seignories. The fish, which are carp, tench, pike, eels, and two other sorts called *schlein* and *rutin*, are caught by laying nets over the holes. Mr Keyser tells us, that upon the ringing of a bell at Zirknitz, when the waters begin to fall, the peasants, both men and women, run to the pools quite naked, notwithstanding both the clergy and magistrates have used their utmost endeavours to suppress so indecent a custom. When the water runs off early in the year, in about three weeks after it is gone there is good grass on the bottom, which is mowed down, and the bottom afterwards ploughed and sowed with millet. If the water runs not off early, nothing can be sown; and if it returns soon, the seed is lost. With respect to its return, the water at first burles out of some pits on the south side with great violence, a little rain always falling at the same time; but afterwards (when the rain falls heavier, and it thunders at the same time so loud as to shake the earth) it breaks out through all the apertures with great force, inasmuch that the lake is filled in 18 or 24 hours, at which time it is in a manner covered with wild fowl; such as geese, ducks, &c. After the millet-harvest, all manner of game is hunted, caught, or killed in it. On the south side are two caverns, out of which, when it thunders, water issues with astonishing violence; and if it happens in harvest, a great many naked, black, and blind, but fat ducklings, are brought up with the water, which in 14 days receive their sight, and are covered with feathers.

ZIZANIA, in botany; a genus of plants of the class *monocotyledon*, order *hexandria*; and in the natural system arranged under the 4th order, *Gramina*. There is no male calyx; the corolla is a bivalved, beardless glume, intermixed with the female flowers; there is no female calyx, the corolla is an univalved, crested, and aristated glume; the style is bipartite, and there is one seed covered with the plaited corolla. There are three species; the aquatic, the pulustris, and terrestris, none of which are natives of Britain.

ZODIAC, in astronomy, a broad circle, whose middle is the ecliptic, and its extremes two circles parallel thereto, at such a distance from it as to bound or comprehend the excursions of the sun and planets, (see ASTRONOMY). It is a curious enough fact, that the solar division of the Indian zodiac is the same in substance with that of the Greeks, and yet that it has not been borrowed either from the Greeks or the Arabians. The identity, or at least striking similarity, of the division, is universally known; and M. Montucla has endeavoured to prove, that the Bramins received it from the Arabs. His opinion, we believe, has been very generally admitted; but in the second volume of the Asiatic Researches, the accomplished president Sir William Jones has proved unanswerably, that neither of these nations borrowed that division from the other; that it has been known among the Hindoos from time immemorial; and that it was probably invented by the first progenitors of that race, whom he considers as the most ancient of mankind, before their dispersion. The question is not of importance sufficiently general, straitened as we are by the limits prescribed us, for our entering into the dispute; but we think it

Zirknit-
zer-see
Zodiac.

Zogea,
Zone.

our duty to mention it, that our astronomical readers, if they think it worth their while, may have recourse to the original writers for further information.

ZOEGEA, in botany; a genus of plants of the class *syngenesia*, and order *polygamia frustranea*. The receptacle is bristly; the pappus setaceous; the corollulæ of the radius ligulated; the calyx imbricated. There are two species, the capensis and the leptaura, neither of which are natives of Britain.

ZONE, in geography and astronomy, a division of the terraqueous globe with respect to the different degrees of heat found in the different parts thereof. The zones are

denominated torrid, frigid, and temperate. The torrid zone is a band, surrounding the terraqueous globe, and terminated by the two tropics. Its breadth is 46° 58'. The equator, running through the middle of it, divides it into two equal parts, each containing 23° 29'. The ancients imagined the torrid zone uninhabitable. The temperate zones are contained between the tropics and the polar circles. The breadth of each is 43. 2. The frigid zones are segments of the surface of the earth, terminated, one by the antarctic, and the other by the arctic circle. The breadth of each is 46. 58.

Z O O L O G Y,

Mammalia. IS that part of Natural History which relates to *Animals*.

In order to abridge the study of zoology, many methods of reducing animals to classes, genera, and species, have been invented: But as that of Linnæus is undoubtedly the best, the most extensive, and the most generally adopted, we shall give a brief account of it.

Linnæus divides the whole animal kingdom into six classes. The characters of these six classes are taken from the internal structure of animals, in the following manner:

CLASS I. MAMMALIA, includes all animals that suckle their young. The characters of this class are these:—The *heart* has two ventricles and two auricles; the *blood* is red and warm; and the animals belonging to it are *viviparous*.

CLASS II. AVES, or **BIRDS**. The characters are the same with those of Class I. excepting that the animals belonging to it are *oviparous*. See **BIRD**, and **ORNITHOLOGY**.

CLASS III. AMPHIBIA, or **AMPHIBIOUS ANIMALS**. The *heart* has but *one ventricle* and *one auricle*; the *blood* is red and cold; and the animals belonging to this class have the command of their *lungs*, so that the intervals between *inspiration* and *expiration* are in some measure *voluntary*. See **AMPHIBIOUS**.

CLASS IV. PISCES, or **FISHES**. The *heart* has the same structure, and the *blood* the same qualities, with those of the *Amphibia*; but the animals belonging to this class are easily distinguished from the *Amphibia*, by having no such voluntary command of their *lungs*, and by having external *branchiæ* or *gills*. See **FISH**, and **ICHTHYOLOGY**.

CLASS V. INSECTA, or **INSECTS**. The *heart* has *one ventricle*, but *no auricle*; the *blood* is cold and white; and the animals are furnished with *antennæ* or *feelers*. See **INSECT**.

CLASS VI. VERMES, or **WORMS**. The characters are the same with those of Class V. only the animals have no *antennæ*, and are furnished with *tentacula*.

The *First Class*, **MAMMALIA**, is subdivided into seven **ORDERS**; the characters of which are taken from the number, structure, and situation of the **TEETH**.

ORDER I. The **PRIMATES** have four incisors, or *fore-teeth*, in each jaw, and one *dog tooth*. N. B. By *one dog-tooth*, Linnæus means one on each side of the fore-teeth in both jaws.—This order includes four genera, *viz.* Homo, Simia, Lemur, Vespertilio.

ORDER II. The **BRUTA** have no *fore-teeth* in either **JAW**. This order includes seven genera, *viz.* Rhinoceros, Elephas, Trichechus, Bradypus, Myrmecophaga, Manis, Dasybus.

ORDER III. The **FERÆ** have, for the most part, six *conical fore-teeth* in each jaw. This order includes 10 genera, *viz.* Phoca, Canis, Felis, Viverra, Mustela, Ursus, Didelphis, Talpa, Sorex, Erinaceus.

ORDER IV. The **GLIRES** have two fore-teeth in each jaw, and no *dog-teeth*.—This order includes 10 genera, *viz.* Hystrix, Lepus, Castor, Mus, Sciurus, Myoxus, Cavia, Arctomys, Dypus, Hyrox.

ORDER V. The **PECORA**, have no *fore-teeth* in the upper jaw, but 6 or 8 in the under-jaw.—This order includes 8 genera, *viz.* Camelus, Moschus, Giraffa, Cervus, Antelope, Capra, Ovis, Bos.

ORDER VI. The **BELLUÆ**, have *obtuse fore-teeth* in each jaw.—This order includes 4 genera, *viz.* Equus Hippopotamus, Sus, Tapir.

ORDER VII. The **CETE**, or *whale kind*, have no uniform character in their teeth, being very different in the different genera; but are sufficiently distinguished from the other orders of **Mammalia**, by living in the ocean, having pectoral fins, and a siphula or spiraculum upon the head.—This order includes 4 genera, *viz.* Monodon, Balæna, Physter, Delphinus. See **CETACEOUS**.

The *generic* characters of the **Mammalia** are, like those of the orders, almost entirely taken from the **TEETH**, excepting the *Vespertilio*, which, besides the character of the order derived from the teeth, has this further mark, that there is a membrane attached to the feet and sides, by means of which the creature is enabled to fly:—the *Hystrix*, whose body is covered with sharp spines:—and the whole order of *Pecora*, whose genera, besides the characters taken from the teeth, are distinguished into those which have *horns*, those which have *no horns*, and by peculiarities in the horns themselves.

The *specific* characters are very various, being taken from any part of the body which possesses a peculiar uniform mark of distinction. As examples of these characters are to be found under the proper name of each genus, it is unnecessary to say any thing further concerning them in this place.

The *Second Class*, **AVES**, is subdivided into six **ORDERS**; the characters of which are taken chiefly from the structure of the **BILL**.

ORDER I. The **ACCIPITRES**, have a **HOOKE**D **BILL**, the superior mandible, near the base, being extended on each side beyond the inferior; and in some it is armed

armed with *teeth*.—This order includes four species, viz. Vultur, Falco, Strix, Lanius.

ORDER II. The PICÆ, have a convex, compressed BILL, resembling a knife.—This order contains 23 genera, viz. Trochilus, Certhia, Upupa, Glaucoptis, Buphaga, Sitta, Oriolus, Coracias, Gracula, Corvus, Paradisea, Ramphastos, Trogon, Ptiliacus, Crotophaga, Picus, Yunx, Cuculus, Bucco, Bucerus, Alcedo, Merops, Todus.

ORDER III. The ANSERES, have a smooth BILL, broadest at the point, covered with a smooth skin, and furnished with teeth: The *tongue* is fleshy; and the toes are palmated or webbed.—This order includes 13 genera, viz. Anas, Mergus, Phacton, Ploctus, Rhyncops, Diomedea, Aptenodyta, Alca, Procellaria, Pelecanus, Larus, Sterna, Colymbus.

ORDER IV. The GRALLÆ, have a somewhat cylindrical BILL: The tail is short, and the thighs are naked. This order contains 20 genera, viz. Phœnicopterus, Platalea, Palamedea, Mycteria, Tantalus, Ardea, Corirra, Recurvirostra, Scolopax, Tiinga, Fulica, Parra, Rallus, Vaginalis, Psochia, Cancroma, Scopus, Glareola, Hæmatopus, Charadrius.

ORDER V. The GALLINÆ, have a convex BILL; the superior mandible is vaulted over the inferior: The *nostrils* are half covered with a convex cartilaginous membrane; and the *feet* are divided, but connected, at the inmost joint.—This order contains 10 genera, viz. Otis, Struthio, Didus, Pavo, Meleagris, Penelope, Cix, Phasianus, Numida, Tetrao.

ORDER VI. The PASSERES, have a conical sharp-pointed BILL; and the *nostrils* are oval, wide, and naked.—This order contains 17 genera, viz. Loxia, Colius, Fringilla, Phytotoma, Emberiza, Caprimulgus, Hirundo, Pipra, Turdus, Ampelis, Tanagra, Mucicapa, Parus, Motacilla, Alauda, Sturnus, Columba.

The *generic* characters of this class are taken from peculiarities in the *bill*, the *nostrils*, the *tongue*, the *feet*, the *feathers*, the *face*, the *figure* of the *body*. &c.

The characters which serve to distinguish the *species* are very various: For example, the *colour* of the particular *feathers* or parts of *feathers*; *crosses* of feathers on the head, disposed in different manners; the *colour* of the *cere* or *wax*; the *colour* of the *feet*; the *shape* and *length* of the *tail*; the *number*, *situation*, &c. of the *toes*; the *colour* and *figure* of the *bill*, &c.

The *Third Class*, AMPHIBIA, is divided into two ORDERS.

ORDER I. The REPTILES, have four *feet*, and breath by the *mouth*.—This order contains four genera, viz. Testudo, Draco, Lacerta, Rana.

ORDER II. The SERPENTES, have no *legs*, and breath by the *mouth*.—This order contains six genera, viz. Crotalus, Boa, Coluber, Anguis, Amphibæna, Cæcilia.

The *generic* characters of this class are taken from the general figure of the *body*; from their having *tails* or *no tails*; being covered with a *shell*; having *teeth* or *no teeth*, in the *mouth*; being furnished with *lungs*; having *covered* or *naked* bodies; from the *number*, *situation*, and *figure* of the *scuta* and *scales*; from the *number* and *situation* of the *spiracula*; from the *situation* of the *mouth*, &c.

The *specific* characters are so very various, that it would be superfluous to enumerate them.

The *Fourth Class*, PISCES, is subdivided into six OR-

DERs, the characters of which are taken from the situation of the *belly-fins*.

ORDER I. The APODES, have no *belly-fins*.—This order contains eight genera, viz. Muræna, Gymnotus, Trichiurus, Anachichas, Ammodytes, Ophidium, Stromateus, Xiphias, Sternoptyx, Leptocephalus.

ORDER II. The JUGULARES, have the *belly fins* placed before the *pectoral fins*.—This order includes five genera, viz. Callionymus, Uranoscopus, Trachinus, Gadus, Blennius, Kurtus.

ORDER III. The THORACICI, have the *belly-fins* placed under the *pectoral fins*.—This order comprehends 19 genera, viz. Cepola, Echeneis, Coryphæna, Gobius, Cottus, Scorphæna, Zeus, Pleuronectes, Chætodon, Sparus, Scarus, Labrus, Scizæna, Perca, Gasterosteus, Scomber, Centrogastr, Mullus, Trigla.

ORDER IV. The ABDOMINALES, have the *belly-fins* placed behind the *pectoral fins*.—This order contains 16 genera, viz. Cobitis, Amia, Silurus, Teuthis, Loricaria, Salmo, Fistularia, Esox, Elops, Argentina, Atherina, Mugil, Exocætus, Polynemus, Clupea, Cyprinus.

ORDER V. The BRANCHIOSTEGI, have the *gills* destitute of bony rays.—This order contains 10 genera, viz. Mormyrus, Ostracion, Tetrodon, Diodon, Syngnathus, Pegasus, Centricus, Balistes, Cyclopterus, Lophius.

ORDER VI. The CHONDROPTERYGII, have cartilaginous *gills*.—This order contains five genera, viz. Acipenser, Chimæra, Squalus, Raia, Petromyzon.

The *generic* characters of this class are taken from peculiarities in the *head*, the *mouth*, the *teeth*, the *nostrils*, the *rays* in the *membrane* of the *gills*, the *eyes*, the general *figure* of the *body*, the *figure* of the *tail*, the *situation* of the *spiracula*, &c.

The *specific* characters are taken from peculiarities in all the parts above enumerated, and many others.

See further the articles FISH and ICHTHOLOGY.

The *Fifth Class*, INSECTA, is subdivided into seven ORDERS, the characters of which are taken from the wings. See the article INSECT.

ORDER I. The COLEOPTERA, have four wings, the two superior ones being crustaceous, and furnished with a *straight future*.—This order comprehends 47 genera, viz. Scabæus, Lucanus, Dermelles, Melyris, Byrrhus, Silpha, Ritoma, Hydrophilus, Hister, Pausus, Boltrichus, Anthrenus, Nitidula, Coccinella, Curculio, Brentus, Attelabus, Erodius, Staphylinus, Scaurus, Zyria, Meloe, Tenebrio, Cassida, Opatrum, Mordella, Chrysomela, Horia, Apalus, Manticora, Pimelia, Gyrimus, Cucujus, Cryptocephalus, Bruchus, Ptinus, Hispa, Buprestis, Necydalis, Lampyrus, Cantharis, Notoxus, Elater, Calopus, Alurnus, Carabus, Lytta, Serropalpus, Cerambyx, Lepura, Rhinomacer, Zonitis, Cicindela, Dyticus, Forficula.

ORDER II. The HEMIPTERA, have four wings, the two superior ones being *semicrustaceous*, and *incumbent*, i. e. the *interior edges* lie above one another.—This order includes 14 genera, viz. Blatta, Pncumora, Mantis, Gryllus, Fulgora, Cicada, Notonecta, Nepa, Cimex, Macrocephalus, Aphis, Chermes, Coccus, Thrips.

Insecta,
Vermes.

ORDER III. The LEPIDOPTERA, have *four wings*, all of them imbricated with *scales*.—This order contains three genera, *viz.* Papilio, Sphinx, Phalæna.

ORDER IV. The NEUROPTERA, have *four wings*, interwoven with veins, like a piece of *network*, and no *fling* in the *caus*.—This order includes seven genera, *viz.* Libella, Ephemeræ, Hemerobius, Myrmelion, Phryganea, Panorpa, Rophidia.

ORDER V. The HYMENOPTERA, have the same characters with the former, only the *anus* is armed with a *sting*. But this mark is peculiar to the *females* and *neuters*; for the males have no *sting*.—This order comprehends 15 genera, *viz.* Cynips, Tentredo, Sirex, Ichneumon, Sphecx, Scolia, Thynnus, Leucopis, Tiphia, Chalcis, Chrysis, Vespa, Apis, Formica, Mutilla.

ORDER VI. The DIPTERA, have *two wings*, and two *clavated balancers* or *balances* behind each wing.—This order contains 12 genera, *viz.* Diopis, Tipula, Musca, Tabanus, Empis, Conops, Oestrus, Ailus, Stomoxys, Culex, Bombylius, Hippobosca.

ORDER VII. The APTERA, have *no wings*.—This order contains 15 species, *viz.* Lepisma, Podura, Termes, Pediculus, Pulex, Acarus, Hydrachna, Aranea, Phalangium, Scorpio, Cancer, Monoculus, Oniscus, Scolopendra, Julus. See further the articles ENTOMOLOGY and INSECT.

The *Sixth Class*, VERMES, is divided into five ORDERS.

ORDER I. The INTESTINA, are the most *simple animals*, being perfectly *naked*, and without *limbs* of any kind.—This order contains 21 genera, *viz.* Aseris, Trichocephalus, Uncinaria, Tilaria, Scolex, Ligula, Linguatula, Strongylus, Echinorhynchus, Hæruca, Cucullanus, Caryophyllæus, Fasciola, Tænia, Furia, Myxine, Gordius, Hirudo, Lumbricus, Sipunculus, Planaria.

ORDER II. The MOLLUSCA, are likewise *simple na-*

ked animals, without any *shell*; but they are *brachi-ated*, or furnished with a kind of *limbs*.—This order comprehends 31 genera, *viz.* Aëtinia, Clava, Mammaria, Pedicellaria, Aseidia, Salpa, Dasyfa, Pterotrachea, Limax, Aplysia, Doris, Tethis, Holothuria, Terebella, Triton, Sepia, Clio, Lobaria, Lernæa, Scyllæa, Glaucus, Aphrodita, Amphitrite, Spio, Nereis, Nais, Physiphora, Medusa, Luccernaria, Asterias, Echinus.

ORDER III. The TESTACEA, have the same characters with those of Order II. but are covered with a *shell*.—This order includes 36 genera, *viz.* Chiton, Lepas, Pholas, Mya, Solen, Tellina, Cardium, Macra, Donax, Venus, Spondylus, Chama, Arca, Ostrea, Anomia, Mytilus, Pinna, Argonauta, Nautilus, Conus, Cypræa, Bulla, Voluta, Buccinum, Strombus, Murex, Trochus, Turbo, Helix, Nerita, Halionis, Patella, Dentalium, Serpula, Teredo, Sabella.

ORDER IV. The ZOOPHYTA, are *compound animals*, furnished with a kind of *flowers*, and having a vegetating *root* and *stem*.—This order contains 15 genera, *viz.* Tubipora, Madrepora, Millepora, Cellepora, Isis, Antipathes, Gorgonia, Alcyonium, Spongia, Flustra, Tubularia, Corallina, Sertularia, Penatula, Hydra. See ANIMAL Flower.

ORDER V. The INFUSORIA, consists of very small *simple animals*.—This order contains 15 genera, *viz.* Brachionus, Vorticella, Trichoda, Cercaria, Leucopera, Gonium, Colpoda, Paramecium, Cyclidium, Eufaria, Vibrio, Enchelis, Bacillaria, Volvox, Monas.

For more particular information concerning the several branches and subjects of zoology, the reader may consult the various articles above referred to, and he will find most of the genera described in their order in the alphabet.

Z O R

ZOOPHYTE, in natural history, the 4th order of the class of *Vermes*. See ZOOLOGY.

ZOOTOMY, the art of dissecting animals or living creatures, being the same with anatomy. See ANATOMY, and COMPARATIVE Anatomy.

ZORILLE, in zoology, a species of weasel, having the back and sides marked with short stripes of black and white, the last tinged with yellow; the tail long and bushy, partly white and partly black; the legs and belly black. This animal inhabits Peru, and other parts of South America: its pestilential vapour overcomes even the panther of America, and stupefies that formidable enemy.

ZOROASTER, or ZERDUSHT, a celebrated ancient philosopher, said to have been the reformer or the founder of the religion of the magi. It is wholly uncertain to how many eminent men the name of Zoroaster belonged. Some have maintained that there was but one Zoroaster, and that he was a Persian; others have said that there were six eminent founders of philosophy of this name. Ham the son of Noah, Moses, Osiris, Mithras, and others, both gods and men, have by different writers been asserted to have been the same with Zoroaster. Many different opinions have also been advanced concerning the time in which he flourished. Aristotle and Pliny fix his date at so remote a period as 6000 years before the death of Plato. According to Laetius, he flourished 600 years before the Trojan

Z O S

war; according to Suidas, 500. If, in the midst of so much uncertainty, any thing can be advanced with the appearance of probability, it seems to be this; that there was a Zoroaster, a Perso-Median, who flourished about the time of Darius Hystaspes; and that besides him there was another Zoroaster, who lived in a much more remote period among the Babylonians, and taught them astronomy. The Greek and Arabian writers are agreed concerning the existence of the Persian Zoroaster; and the ancients unanimously ascribe to a philosopher, whom they call Zoroaster, the origin of the Chaldean astronomy, which is certainly of much earlier date than the time of Hystaspes: it seems, therefore, necessary to suppose a Chaldean Zoroaster distinct from the Persian. Concerning this Zoroaster, however, nothing more is known, than that he flourished towards the beginning of the Babylonish empire, and was the father of the Chaldean astrology and magic. All the writings that have been ascribed to Zoroaster are unquestionably spurious.

ZOSTERA, in botany; a genus of plants of the class gynandria, order polyandria; and in the natural system arranged under the second order, Piperite. The spatix is linear, and fertile only on one side; there is no calyx nor corolla; the stamina are alternate; the seeds solitary and alternate. There are two species, the marina and oceanica; neither of which is a native of Britain.

ZOSIMUS, an ancient historian who lived at the end of the fourth and beginning of the fifth centuries. There are six books of his history extant; in the first of which he runs over the Roman affairs in a very succinct manner from Augustus to Dioclesian; the other five are written more diffusely. Zosimus was a zealous Pagan; whence we find him frequently inveighing with great bitterness against the Christian princes, particularly against Constantine the Great, and the elder Theodosius. His history has been published with the Latin version of Leunclavius at Frankfurt, 1590, with the other minor historians of Rome, in folio; and at Oxford in 8vo, 1679.

ZUG, a canton of Switzerland, bounded on the east and north by that of Zurich, on the south by Schweiz and Lucern, and on the west by the canton of Lucern and the Frey-Amt or Free Provinces. It is not above 12 miles either way; but very populous and fruitful, yielding wine, wheat, chestnuts, and other fruits, in its vales, and excellent pasture on its mountains. The inhabitants of this canton are staunch Roman Catholics. It lies in the diocese of Constance, and its government is democratical. There are two lakes in it abounding in fish, particularly large carps, pikes, and a species of trouts called *rotels*; as well as several woods full of game. Zug, which gives name to it, and is its capital, stands on the east side of a lake of the same name, about seven miles long; and is a strong neat town, containing a priory and two convents.

ZUINGLIUS (Ulricus), an able and zealous reformer, who laid the foundation of a separation from Rome in Switzerland, at the same time that Luther did the like in Saxony, was born at Wildehausen in 1487. While he officiated as preacher at Zurich, a Franciscan sent by Leo X. came to publish indulgences there; against which Zuinglius, after the example of Luther, declaimed powerfully. In the course of this opposition he started a new doctrine, which he called *Evangelical Truth*; and from the beginning of 1519 to 1523, he preached not only against indulgences, but against other articles of the Romish church. But though Zuinglius made no less progress than Luther, he yet conducted himself with more moderation and prudence; and wishing to have the concurrence of the civil powers, procured two assemblies to be called at Zurich: by the first, he was authorized to proceed as he had begun; and by the second, the outward worship and ceremonies of the church of Rome were abolished. During these transactions, Zuinglius published several books in defence of his doctrines; but treating of the eucharist, and prescribing a form of celebrating the Lord's Supper different from Luther, he was involved in violent disputes with the rest of his reforming brethren. Interpreting the words *hoc est corpus meum*, by *hoc significat corpus meum*, he maintained, that the body and blood of Christ are not really present in the eucharist; and that the bread and wine are nothing more than external signs or symbols, designed to excite in the minds of Christians the remembrance of the sufferings of the Divine Saviour, and of the benefits which arise from them. This opinion, which was afterwards so plausibly supported by the celebrated Hozley (see *Supper of the Lord*), gave offence to Calvin as well as to Luther; but the doctrines of Zuinglius, which were most obnoxious to that eminent reformer, were those which deny *election* and *reprobation*, and make the church as a society wholly dependent on the state. Respecting the divine decrees, the opinion of Zuinglius and his followers differed very little from that of the PELAGIANS: for he maintained that heaven is open to all who live according to the dictates of right reason; and he seems to have denied the doctrine of original sin. Instead of de-

claring with Calvin, that the church is a separate independent body, vested with the right of legislation for itself, Zuinglius ascribed to the civil magistrate an absolute and unbounded power in religious matters, allowing at the same time a certain subordination among the ministers of the church. This was abundantly agreeable to the magistrates of Zurich; but the rest of the Swiss cantons disallowing of their proceedings, other assemblies were called, and things tending to tumult, both sides had recourse to arms; when Zuinglius, who began as a preacher, died in arms as a soldier, in 1531. His work amount to four vols folio.

ZURICHI, a canton of Switzerland bounded to the north by Swabia and the canton of Schaffhausen; to the south by the town and territory of Rapperswil and the cantons of Switz and Zug; to the east by the Thurgau, Toggenburg, and Uznach; and to the west by the bailiages and county of Baden. It is about 60 miles from north to south, and 48 from east to west. With respect to its face, air, and soil, it is said to be an epitome of all Switzerland, as containing in it hills, valleys, plains, cornlands, vineyards, lakes, and rivers. The winters have a tartness at first, but the longer they are kept the more agreeable they are. The other products are excellent fruits, corn, pasture, fine clay, chalk, several coloured earths, pit-coal, turf, and sulphur. There are also some mineral springs in the canton; and of the lakes, that of Zurich is the most considerable. The reformation was introduced here by Zuinglius in the year 1517. This canton is the first in rank, and inferior only to that of Bern in extent, power, and wealth; in consequence of which, its representatives preside in the general diets, when held in any place belonging in common to the cantons; and the affairs relating to the whole confederacy are transacted in its offices. Its quota, for the defence of the several members of the confederacy, is 1,400 men. Of one of the two armies raised on these occasions, it nominates one of the commanders in chief, as Lucern does the other. Its revenue is said to be about 150,000 crowns a-year; of which, one year with another, two thirds are expended in the charges of government, and the rest laid up in the treasury. It can bring 50,000 fighting men into the field at a very short warning.

ZURICH, the capital of a canton of the same name in Switzerland, stands in a pleasant country, near where the river Aa issues from the lake that takes its name from the town, 23 miles from Schaffhausen, and 114 from Geneva. After having been ruined by Attila the Hun, it is said to have been restored by Thunicus, son of Theodoric king of the Goths, from whom it took the name of *Thuricum*, corrupted afterwards into that of *Zurich*. It is fortified in the modern way, and has wide ditches, faced with free stone. There are five arsenals in it, well stored with arms and artillery; an academy or college, having 15 professors; a museum, or chamber of rarities; a stately town-house, the pillars in the front of which are of black marble, streaked with white; and a town library. The sovereignty and administration of all affairs are lodged in the greater and lesser council, out of which are chosen the city-officers, as the councils are out of the 13 companies of burghers. There are several other councils or colleges, each of which has its particular department. Here are a great variety of silk, woollen, linen, cotton, and other manufactories; this being the place of the greatest trade in all Switzerland. The town is well supplied with provisions by and from its lake. The streets are neat, and houses well built, but not magnificent. In the town-library are several letters to Bulinger from lady Jane Gray daughter to the duke of Suffolk. In one of the arsenals is the figure of William Tell, dressed and armed

Zurich. armed in the ancient Swiss manner, with the cross-bow whence he shot the arrow that struck the apple off his child's head.

Both men and women are so fond of music, that there are few of them that cannot play on some instrument. If a burgher goes out of town, or a peasant enters it, without a sword, they are liable to be fined. No persons, whatever their rank or office may be, are exempted from the sumptuary laws. The burghers, who are the same as the edvoyers at Bern, have the title of excellence. The hospitals here are very neat and well endowed; but they do not affect the ridiculous vanity of lodging the poor in palaces. Not only in this town and canton, and other parts of Switzerland, but also among the Grisons, the ministers all preach covered. The country about the town is very pleasant and fruitful; for both which it is not a little indebted to the lake, that extends 24 miles in length, and about two or three in breadth. The water is of a green colour, supposed to be owing to the melted snow that falls into it from the adjacent mountains. That part of it next Zurich is called the *Lower Lake*, and the other end the *Upper*. The cathedral, or great church here, is collegiate. The present city is said to owe its origin to a nunnery, founded by the emperor Lewis I. near where the ancient Tigurum stood. E. Long. 8. 30. N. Lat. 47. 20.

What may be reckoned one of the greatest curiosities of Zurich is the pump invented and erected here by H. Andreas Wirtz, a tinplate worker of this place. The invention shows him to be a person of very uncommon mechanical knowledge and sagacity. As it is a machine which operates on a principle widely different from all other hydraulic machines, and is really excellent in its kind, we presume that our readers will not be displeas'd with some account of it, although it be rather out of place here, and should have appeared in the article *Water-Works*.

PLDCLII. Fig. 16. is a sketch of the section of the machine, as it was first erected by Wirtz at a dye house in Limmat, in the suburbs or vicinity of Zurich. It consists of a hollow cylinder, like a very large grindstone, turning on a horizontal axis, and partly plunged in a cistern of water. The axis is hollow at one end, and communicates with a perpendicular pipe CBZ, part of which is hid by the cylinder. This cylinder or drum is formed into a spiral canal by a plate coiled up within it like the main spring of a watch in its box; only the spires are at a distance from each other, so as to form a conduit for the water of uniform width. This spiral partition is well joined to the two ends of the cylinder, and no water escapes between them. The outermost turn of the spiral begins to widen about $\frac{1}{4}$ th of a circumference from the end, and this gradual enlargement continues from Q to S nearly a semicircle: this part may be called the *HORN*. It then widens suddenly, forming a *SCOOP* or shovel SS'. The cylinder is supported so as to dip several inches into the water, whose surface is represented by VV'.

When this cylinder is turned round its axis in the direction ABEO, as expressed by the two darts, the scoop SS' dips at V, and takes up a certain quantity of water before it emerges again at V. This quantity is sufficient to fill the taper part SQ, which we have called the *HORN*; and this is nearly equal in capacity to the outermost uniform spiral round.

After the scoop has emerged, the water passes along the spiral by the motion of it round the axis, and drives the air before it into the rising-pipe, where it escapes.—In the mean time, air comes in at the mouth of the scoop; and when the scoop again dips into the water, it again takes in some. Thus there is now a part filled with water and a part fil-

led with air. Continuing this motion, we shall receive a second round of water and another of air. The water in any turn of the spiral will have its two ends on a level; and the air between the successive columns of water will be in its natural state; for since the passage into the rising pipe or MAIN is open, there is nothing to force the water and air into any other position. But since the spires gradually diminish in their length, it is plain that the column of water will gradually occupy more and more of the circumference of each. At last it will occupy a complete turn of some spiral that is near the centre; and when sent farther in, by the continuance of the motion, some of it will run back over the top of the succeeding spiral. Thus it will run over at K₄ into the right hand side of the third spiral. Therefore it will push the water of this spire backwards, and raise its other end, so that it also will run over backwards before the next turn be completed. And this change of disposition will at last reach the first or outermost spiral, and some water will run over into the horn and scoop, and finally into the cistern.

But as soon as water gets into the rising pipe, and rises a little in it, it stops the escape of the air when the next scoop of water is taken in. Here are now two columns of water acting against each other by hydrostatic pressure and the intervening column of air. They must compress the air between them, and the water and air-columns will now be unequal. This will have a general tendency to keep the whole water back, and cause it to be higher on the left or rising side of each spire than on the right descending side. The excess of height will be just such as produces the compression of the air between that and the preceding column of water. This will go on increasing as the water mounts in the rising-pipe; for the air next to the rising-pipe is compressed at its inner end with the weight of the whole column in the main. It must be as much compressed at its outer end. This must be done by the water column without it; and this column exerts this pressure partly by reason that its outer end is higher than its inner end, and partly by the transmission of the pressure on its outer end by air, which is similarly compressed from without. And thus it will happen that each column of water, being higher at its outer than at its inner end, compresses the air on the water-column beyond or within it, which transmits this pressure to the air beyond it, adding to it the pressure arising from its own want of level at the ends. Therefore the greatest compression, viz. that of the air next the main, is produced by *the sum of all the transmitted pressures*; and these are the sum of all the differences between the elevations of the inner ends of the water columns above their outer ends: and the height to which the water will rise in the main will be just equal to this sum.

Draw the horizontal lines K'K₁, K'K₂, K'K₃, &c. and m₁n, m₂n, m₃n, &c. Suppose the left hand spaces to be filled with water, and the right hand spaces to be filled with air. There is a certain gradation of compression which will keep things in this position. The spaces evidently decrease in arithmetical progression; so do the hydrostatic heights and pressures of the water columns. If therefore the air be dense in the same progression, all will be in hydrostatic equilibrium. Now this is evidently producible by the mere motion of the machine; for since the density and compression in each air column is supposed inversely as the bulk of the column, the absolute quantity of air is the same in all; therefore the column first taken in will pass gradually inwards, and the increasing compression will cause it to occupy precisely the whole right hand side of every spire. The gradual diminution of the water columns will be produced during the motion by the water running over backwards at the

the top, from spire to spire, and at last coming out by the scoop.

It is evident that this disposition of the air and water will raise the water to the greatest height, because the hydrostatic height of each water column is the greatest possible, viz. the diameter of the spire. This disposition may be obtained in the following manner: Take CL to CB as the density of the external air to its density in the last column next the rising-pipe or main; that is, make CL to CB as 33 feet (the height of the column of water which balances the atmosphere), to the sum of 33 feet and the height of the rising-pipe. Then divide BL into such a number of turns, that the sum of their diameters shall be equal to the height of the main; then bring a pipe straight from L to the centre C. The reason of all this is very evident.

But when the main is very high, this construction will require a very great diameter of the drum or many turns of a very narrow pipe. In such cases it will be much better to make the spiral in the form of a cork-screw, as in fig. 17. instead of this flat form like a watch-spring. The pipe which forms the spiral may be lapped round the frustum of a cone, whose greatest diameter is to the least (which is next to the rising pipe) in the same proportion that we assigned to CB and CL. By this construction the water will stand in every round so as to have its upper and lower surfaces tangents to the top and bottom of the spiral, and the water columns will occupy the whole ascending side of the machine, while the air occupies the descending side.

This form is vastly preferable to the flat: it will allow us to employ many turns of a large pipe, and therefore produce a great elevation of a large quantity of water.

The same thing will be still better done by lapping the pipe on a cylinder, and making it taper to the end, in such a proportion that the contents of each round may be the same as when it is lapped round the cone. It will raise the water to a greater height (but with an increase of the impelling power) by the same number of turns, because the vertical or pressing height of each column is greater.

Nay, the same thing may be done in a more simple manner, by lapping a pipe of uniform bore round a cylinder. But this will require more turns, because the water columns will have less differences between the heights of their two ends. It requires a very minute investigation to show the progress of the columns of air and water in this construction, and the various changes of their arrangement, before one is attained which will continue during the working of the machine.

We have chosen for the description of the machine that construction which made its principle and manner of working most evident, namely, which contained the same material quantity of air in each turn of the spiral, more and more compressed as it approaches to the rising-pipe. We should otherwise have been obliged to investigate in great detail the gradual progress of the water, and the frequent changes of its arrangement, before we could see that one arrangement would be produced which would remain constant during the working of the machine. But this is not the best construction. We see that, in order to raise water to the height of a column of 34 feet, which balances the atmosphere, the air in the last spire is compressed into half its bulk; and the quantity of water delivered into the main at each turn is but half of what was received into the first spire, the rest flowing back from spire to spire, and being discharged at the spout.

But it may be constructed so as that the quantity of water in each spire may be the same that was received into the first; by which means a greater quantity (double in the instance now given) will be delivered into the main, and raised

to the same height by very nearly the same force. — Zurich. This may be done by another proportion of the capacity of the spires, whether by a change of their caliber or of their diameters. Suppose the bore to be the same, the diameter must be made such that the constant column of water, and the column of air, compressed to the proper degree, may occupy the whole circumference. Let a be the column of water which balances the atmosphere, and b the height to which the water is to be raised. Let Λ be to $\Lambda + b$ as 1 to m .

It is plain that m will represent the density of the air in the last spire, if its natural density be 1 , because it is pressed by the column $\Lambda + b$, while the common air is pressed by Λ . Let 1 represent the constant water column, and therefore nearly equal to the air column in the first spire. The whole circumference of the last spire must be $1 + \frac{1}{m}$, in order to hold the water 1 , and the air compressed into the space $\frac{1}{m}$ or $\frac{\Lambda}{\Lambda + b}$.

The circumference of the first spire is $1 + 1$ or 2 . Let D and d be the diameters of the first and last spires; we have $2 : 1 + \frac{1}{m} = D : d$, or $2m : m + 1 = D : d$. Therefore if a pipe of uniform bore be lapped round a cone, of which D and d are the end diameters, the spirals will be very nearly such as will answer the purpose. It will not be quite exact, for the intermediate spirals will be somewhat too large. The conoidal frustum should be formed by the revolution of a curve of the logarithmic kind. But the error is very trifling.

With such a spiral, the full quantity of water which was confined in the first spiral will find room in the last, and will be sent into the main at every turn. This is a very great advantage, especially when the water is to be much raised. The saving of power by this change of construction is always in proportion of the greatest compression of the air.

The great difficulty in the construction of any of these forms is in determining the form and position of the horn and the scoop; and on this greatly depends the performance of the machine. The following instructions will make it pretty easy.

Let ABEO (fig. 18.) represent the first or outermost round of the spiral, of which the axis is C. Suppose it immersed up to the axis in the water VV, we have seen that the machine is most effective when the surfaces KB and On of the water columns are distant the whole diameter EO of the spiral. Therefore let the pipe be first supposed of equal caliber to the very mouth Ee, which we suppose to be just about to dip into the water. The surface On is kept there, in opposition to the pressure of the water column BAO, by the compressed air contained in the quadrant OE, and in the quadrant which lies behind EB. And this compression is supported by the column behind, between this spire and the rising pipe. But the air in the outermost quadrant EB is in its natural state, communicating as yet with the external air. When, however, the mouth Ee has come round to A, it will not have the water standing in it in the same manner, leaving the half space BEO filled with compressed air; for it took in and confined only what filled the quadrant BE. It is plain, therefore, that the quadrant BE must be so shaped as to take in and confine a much greater quantity of air; so that when it has come to A, the space BEO may contain air sufficiently dense to support the column AO. But this is not enough: For when the wide mouth, now at Ae, rises up to the top, the surface of the water in it rises also, because the part AOoa is more capacious,

Which is more obvious than the cylindrical part OE , which succeeds it, and which cannot contain all the water that it does. Since, then, the water in the spire rises above A , it will press the water back from On to some other position $m'n'$; and the pressing height of the water column will be diminished by this rising on the other side of O . In short, the horn must begin to widen, not from B , but from A , and must occupy the whole semicircle ABE ; and its capacity must be to the capacity of the opposite cylindrical side as the sum of BO , and the height of a column of water which balances the atmosphere to the height of that column. For then the air which filled it, when of the common density, will fill the uniform side BEO , when compressed so as to balance the vertical column BO . But even this is not enough; for it has not taken in enough of water. When it dipped into the cistern at E , it carried air down with it, and the pressure of the water in the cistern caused the water to rise into it a little way; and some water must have come over at B from the other side, which was drawing narrower. Therefore when the horn is in the position EOA , it is not full of water. Therefore when it comes into the situation OAB , it cannot be full nor balance the air on the opposite side. Some will therefore come out at O , and rise up thro' the water. The horn must therefore, 1st, Extend at least from O to B , or occupy half the circumference; and, 2^{dly}, It must contain at least twice as much water as would fill the side BEO . It will do little harm though it be much larger; because the surplus of air which it takes in at E will be discharged, as the end E of the horn rises from O to B , and it will leave the precise quantity that is wanted. The overplus water will be discharged as the horn comes round to dip again into the cistern. It is possible, but requires a discussion too intricate for this place, to make it of such a size and shape, that while the mouth moves from E to B , passing through O and A , the surface of the water in it shall advance from E to On , and be exactly at O when the beginning or narrow end of the horn arrives there.

We must also secure the proper quantity of water. When the machine is so much immersed as to be up to the axis in water, the capacity which thus secures the proper quantity of air will also take in the proper quantity of water. But it may be erected so as that the spirals shall not even reach the water. In this case it will answer our purpose if we join to the end of the horn a scoop or shovel QR (fig. 19.), which is so formed as to take in at least as much water as will fill the horn. This is all that is wanted in the beginning of the motion along the spiral, and more than is necessary when the water has advanced to the succeeding spire; but the overplus is discharged in the way we have mentioned. At the same time, it is needless to load the machine with more water than is necessary, merely to throw it out again. We think that if the horn occupies fully more than one-half of the circumference, and contains as much as will fill the whole round, and if the scoop lifts as much as will certainly fill the horn, it will do very well.

N. B. The scoop must be very open on the side next the axis, that it may not confine the air as soon as it enters the water. This would hinder it from receiving water enough.

The following dimensions of a machine erected at Florence, and whose performance corresponded extremely well with the theory, may serve as an example.

The spiral is formed on a cylinder of 10 feet diameter, and the diameter of the pipe is 6 inches. The smaller end of the horn is of the same diameter; and it occupies $\frac{1}{4}$ ths of the circumference, and it is $7\frac{1}{10}$ ths inches wide at the outer end. Here it joins the scoop, which lifts as much water as fills the horn, which contains 4340 Swedish cubic inches, each = 1,577 English. The machine makes 6 turns in a

minute, and raises 1354 pounds of water, or 22 cubic feet, 10 feet high in a minute.

The above account will, we hope, sufficiently explain the manner on which this singular hydraulic machine produces its effect. When every thing is executed by the maxims which we have deduced from its principles, we are confident that its performance will correspond to the theory; and we have the Florentine machine as a proof of this. It raises more than $\frac{3}{4}$ ths of what the theory promises, and it is not perfect. The spiral is of equal caliber, and is formed on a cylinder. The friction is so inconsiderable in this machine, that it need not be mended; but the great excellency is, that whatever imperfection there may be in the arrangement of the air and water columns, this only affects the elegance of the execution, causing the water to make a few more turns in the spiral before it can mount to the height required; but wastes no power, because the power employed is always in proportion to the sum of the vertical columns of water in the rising side of the machine; and the height to which the water is raised by it is in the very same proportion. It should be made to move very slow, that the water be not always dragged up by the pipes, which would cause more to run over from each column, and diminish the pressure of the remainder.

If the rising-pipe be made wide, and thus room be made for the air to escape freely up through the water, it will rise to the height assigned; but if it be narrow, so that the air cannot get up, it rises almost as slow as the water, and by this circumstance the water is raised to a much greater height mixed with air, and this with hardly any more power. It is in this way that we can account for the great performance of the Florentine machine, which is almost triple of what a man can do with the finest pump that ever was made: indeed the performance is so great, that one is apt to suspect some inaccuracy in the accounts. The entry into the rising-pipe should be no wider than the last part of the spiral; and it would be advisable to divide it into four channels by a thin partition, and then to make the rising-pipe very wide, and to put into it a number of slender rods, which would divide it into slender channels that would completely entangle the air among the water. This will greatly increase the height of the heterogeneous column. It is surprising that a machine that is so very promising should have attracted so little notice. We do not know of any being erected out of Switzerland except at Florence in 1778. The account of its performance was in consequence of a very public trial in 1779, and honourable declaration of its merit, by Sig. Lorenzo Ginori, who erected another, which fully equalled it. It is shortly mentioned by Professor Sulzer of Berlin, in the *Sammlungen Vermischten Schriften* for 1754. A description of it is published by the Philosophical Society at Zurich in 1766, and in the descriptions published by the Society in London for the encouragement of Arts in 1776. The celebrated Daniel Bernouilli has published a very accurate theory of it in the *Petersburgh Commentaries* for 1772, and the machines at Florence were erected according to his instructions. Baron Alstromer in Sweden caused a glass model of it to be made, to exhibit the internal motions for the instruction of artists, and also ordered an operative engine to be erected; but we have not seen any account of its performance. It is a very intricate machine in its principles; and an ignorant engineer, nay the most intelligent, may erect one which shall hardly do any thing; and yet, by a very trifling change, may become very powerful. We presume that failures of this kind have turned the attention of engineers from it; but we are persuaded that it may be made very effective, and we are certain that it must be very durable. Fig. 20. is a section of the manner in which the
author

author has formed the communication between the spiral and the rising-pipe. P is the end of the hollow axis which is united with the solid iron axis. Adjoining to P, on the under side, is the entry from the last turn of the spiral. At Q is the collar which rests on the supports, and turns round in a hole of bell-metal. *ff* is a broad flanch cast in one piece with the hollow part. Beyond this the pipe is turned somewhat smaller, very round and smooth, so as to fit into the mouth of the rising-pipe, like the key of a cock. This mouth has a plate *ee* attached to it. There is another plate *dd*, which is broader than *ee*, and is not fixed to the cylindrical part, but moves easily round it. In this plate are four screws, such as *g, g*, which go into holes in the plate *ff*, and thus draw the two plates *ff* and *dd* together, with the plate *ee* between them. Pieces of thin leather are put on each side of *ee*; and thus all escape of water is effectually prevented, with a very moderate compression and friction.

ZUTPHEN, a strong and considerable town of the United Provinces in Guelderland, and capital of a county of the same name. It has a magnificent church, and is surrounded with walls. It was taken by the French in 1672, who in 1674 delivered it up to the States-General. It is situated at the confluence of the rivers Berkel and Yessel, nine miles south-east of Deventer, and 55 east by south of Amsterdam. E. Long. 6. 0. N. Lat. 52. 10.

ZUYDER-ZEE, a great gulph or bay of the German Ocean, which extends from south to north in the United

Provinces, between Friesland, Over-Yessel, Guelderland, and Holland. It is so called from its situation towards the south. It is said that the Zuyder-zee was formerly a lake, and that the land is swallowed up which united North-Holland with Friesland.

ZYGOMA, in anatomy, a bone of the head, or rather an union or assemblage of two processes or eminences of bones; the one from the os temporis, the other from the os malæ: these processes are hence termed the *zygomatic processes*, and the suture that joins them together is denominated the *zygomatic suture*.

ZYGOMATICUS, in anatomy, a muscle of the head, arising from the Os *ZYGOMA*, whence its name, and terminating at the angle of the lips.

ZYGOPHYLLUM, BEAN-CAPER, in botany; a genus of plants of the class of decandria and order monogynia, and in the natural system arranged under the 14th order, *Grui-nales*. There are 11 species, partly shrubby and partly herbaceous plants, all natives of warm climates, though some of them are hardy enough to endure the open air in this country.

ZYMOSIMETER (formed from *ζυμοσις fermentation*, and *μετρον measure*), an instrument proposed by Swammerdam in his book *De Respiratione*, wherewith to measure the degree of fermentation occasioned by the mixture of different matters, and the degree of heat which those matters acquire in fermenting, as also the heat or temperament of the blood of animals.
